Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 2 inches; very gravelly fine sandy loam
Bt—2 to 20 inches; very gravelly sandy clay loam
Bk—20 to 60 inches; very gravelly loam

Minor Components

Atarque and similar soils
Composition: About 5 percent
Slope: 25 to 45 percent
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

Fragua and similar soils
Composition: About 5 percent
Slope: 5 to 25 percent
Depth to restrictive feature: 40 to 60 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: Foothills

Sedillo and similar soils
Composition: About 3 percent
Slope: 5 to 25 percent
Drainage class: Well drained
Ecological site: Foothills

Skyvillage and similar soils
Composition: About 2 percent
Slope: 8 to 25 percent
Depth to restrictive feature: 6 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

342—Waumac-Vessilla-Rock outcrop complex, 5 to 40 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,200 to 6,900 feet (1,890 to 2,103 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Waumac and similar soils: 35 percent
Vessilla and similar soils: 25 percent
Rock outcrop: 20 percent
Minor components: 20 percent

Component Descriptions

Waumac soils

Landscape: Uplands
Landform: Valley floors
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Fan alluvium derived from igneous and sedimentary rock

Slope: 5 to 20 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 6.9 inches (moderate)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Sandy
Potential native vegetation: Indian ricegrass, blue grama, western wheatgrass, alkali sacaton, mesa dropseed, oneseed juniper, twoneedle pinyon
Land capability subclass (nonirrigated): 6s

Typical Profile:
A—0 to 5 inches; loamy fine sand
C—5 to 60 inches; sandy loam

Vessilla soils
Landscape: Uplands
Landform: Hills, ridges, breaks, mesas
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Eolian deposits over slope alluvium over residuum weathered from sandstone
Slope: 5 to 40 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 4 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 1.8 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Indian ricegrass, blue grama, mountain big sagebrush, oak, galleta, sideoats grama
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 3 inches; fine sandy loam
C—3 to 13 inches; fine sandy loam
R—13 to 60 inches; bedrock

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Ledges, escarpments
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Minor Components
Badland
Composition: About 10 percent
Slope: 15 to 35 percent
Depth to restrictive feature: 0 inches to bedrock (paralithic)

Royosa and similar soils
Composition: About 5 percent
Slope: 1 to 8 percent
Drainage class: Somewhat excessively drained
Ecological site: Deep Sand

Menefee and similar soils
Composition: About 5 percent
Slope: 15 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: Shallow

345—Espiritu-Bamac association, 15 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,500 to 6,600 feet (1,676 to 2,012 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Espiritu and similar soils: 50 percent
Bamac and similar soils: 35 percent
Minor components: 15 percent

Component Descriptions

Espiritu soils
Landscape: Uplands
Landform: Fan piedmonts, mesas
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Slope alluvium over colluvium derived from igneous and sedimentary rock
Slope: 15 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 10 percent subrounded cobbles

Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 4.7 inches (low)
Shrink-swell potential: About 3.3 percent (moderate)
Runoff class: High
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Foothills
Potential native vegetation: blue grama, hairy grama, black grama, sideoats grama, New Mexico Feathergrass, galleta, oneseed juniper, sacahuista
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 6 inches; very gravelly fine sandy loam
Bt1—6 to 15 inches; very gravelly sandy clay loam
Bt2—15 to 22 inches; very gravelly sandy clay loam
Bk1—22 to 29 inches; very cobbly sandy clay loam
Bk2—29 to 38 inches; very cobbly sandy clay loam
2C1—38 to 46 inches; fine sandy loam
3C2—46 to 60 inches; very gravelly sandy loam

Bamac soils
Landscape: Uplands
Landform: Fan remnants, hills, ridges, fan remnants
Position on landform: Summits
Position on landform: Side slope, head slope
Parent material: Slope alluvium derived from igneous and sedimentary rock
Slope: 15 to 55 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Very deep
Drainage class: Excessively drained
Slowest permeability: 6.0 to 20 in./hr. (rapid)
Available water capacity: About 1.8 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Medium
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Foothills
Potential native vegetation: blue grama, hairy grama, black grama, sideoats grama, New Mexico Feathergrass, galleta, oneseed juniper, sacahuista
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 3 inches; very gravelly loamy sand
C1—3 to 30 inches; very gravelly loamy sand
C2—30 to 60 inches; stratified very gravelly loamy sand to loamy sand

Minor Components

Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

Cochiti and similar soils
Composition: About 5 percent
Slope: 15 to 40 percent
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Rock outcrop
Composition: About 5 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

346—Espiritu, cobbly-Bamac association, 15 to 40 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,900 to 6,900 feet (1,798 to 2,103 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Espiritu, cobbly and similar soils: 70 percent
Bamac and similar soils: 20 percent
Minor components: 10 percent

Component Descriptions

Espiritu, cobbly soils

Landscape: Uplands
Landform: Fan piedmonts, mesas
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Slope alluvium over colluvium derived from igneous and sedimentary rock
Slope: 15 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 7 percent subrounded cobbles
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 3.3 inches (low)
Shrink-swell potential: About 2.6 percent (low)
Runoff class: High
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)

Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Foothills
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: black grama, blue grama, sideoats grama, hairy grama, needle and thread, true mountain mahogany, wavyleaf oak
Land capability subclass (nonirrigated): 6e

Typical Profile:
A—0 to 2 inches; extremely cobbly sandy loam
Bt—2 to 24 inches; very gravelly sandy clay loam
Bk—24 to 36 inches; extremely gravelly sandy loam
2C—36 to 60 inches; very gravelly loamy sand

Bamac soils
Landscape: Uplands
Landform: Hills, ridges, fan remnants
Position on landform: Shoulders
Position on landform: Side slope, head slope
Parent material: Slope alluvium derived from igneous and sedimentary rock
Slope: 15 to 40 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Very deep
Drainage class: Excessively drained
Slowest permeability: 6.0 to 20 in./hr. (rapid)
Available water capacity: About 2.4 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Medium
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Foothills
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: black grama, blue grama, sideoats grama, hairy grama, needle and thread, true mountain mahogany, wavyleaf oak
Land capability subclass (nonirrigated): 6e

Typical Profile:
A—0 to 3 inches; very gravelly loamy sand
C1—3 to 30 inches; very gravelly loamy coarse sand
C2—30 to 45 inches; loamy sand
C3—45 to 60 inches; very gravelly loamy sand

Minor Components
Cochiti and similar soils
Composition: About 5 percent
Slope: 15 to 40 percent
Drainage class: Well drained

Rock outcrop
Composition: About 3 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

Royosa and similar soils
Composition: About 2 percent
Slope: 1 to 8 percent
Drainage class: Somewhat excessively drained
Ecological site: Deep Sand

348—Wauquie-Rock outcrop complex, 25 to 45 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,000 to 6,800 feet (1,829 to 2,073 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Wauquie and similar soils: 60 percent
Rock outcrop: 20 percent
Minor components: 20 percent

Component Descriptions

Wauquie soils
Landscape: Mountains
Landform: Mountain slopes, hills, mesas, benches, canyons
Position on landform: Backslopes
Position on landform: Mountainflank
Parent material: Slope alluvium over colluvium derived from igneous and sedimentary rock
Slope: 25 to 45 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 3.7 inches (low)
Shrink-swell potential: About 2.2 percent (low)
Runoff class: High
Calcium carbonate maximum: About 3 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Eriogonum, blue grama, skunkbush sumac, slender wheatgrass, bottlebrush squirreltail, wavyleaf oak
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 2 inches; extremely gravelly sandy clay loam
Bt1—2 to 16 inches; very gravelly clay loam
Bt2—16 to 40 inches; very gravelly sandy loam
Bk—40 to 60 inches; extremely gravelly loamy sand

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Escarpments, ledges
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Minor Components
Bamac and similar soils
Composition: About 5 percent
Slope: 15 to 55 percent
Drainage class: Excessively drained
Ecological site: Foothills

Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

Vessilla and similar soils
Composition: About 5 percent
Slope: 5 to 30 percent
Depth to restrictive feature: 6 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

Royosa and similar soils
Composition: About 5 percent
Slope: 1 to 8 percent
Drainage class: Somewhat excessively drained
Ecological site: Deep Sand

353—Cochiti-Espiritu association, 15 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,300 to 6,400 feet (1,615 to 1,951 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Cochiti and similar soils: 50 percent
Espiritu and similar soils: 45 percent
Minor components: 5 percent

Component Descriptions

Cochiti soils
Landscape: Uplands
Landform: Fan remnants
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Slope alluvium derived from igneous and sedimentary rock
Slope: 15 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 3 percent subrounded cobbles
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 3.8 inches (low)
Shrink-swell potential: About 2.5 percent (low)
Runoff class: High
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: blue grama, bottlebrush squirreltail, sideoats grama
Land capability subclass (nonirrigated): 6e

Typical Profile:
A—0 to 4 inches; extremely gravelly loam
Bt—4 to 22 inches; very gravelly clay loam
C—22 to 60 inches; very gravelly loamy sand

Espiritu soils
Landscape: Uplands
Landform: Fan piedmonts, mesas
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Slope alluvium over colluvium derived from igneous and sedimentary rock
Slope: 25 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 3 percent subrounded cobbles
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 2.4 inches (very low)
Shrink-swell potential: About 2.2 percent (low)
Runoff class: High
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)

Ecological site: Foothills
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: black grama, blue grama, sideoats grama, hairy grama, needle and thread, true mountain mahogany, wavyleaf oak
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 3 inches; very gravelly loam
Bt—3 to 16 inches; very gravelly sandy clay loam
Bk—16 to 60 inches; extremely gravelly loamy sand

Minor Components
Teco and similar soils
Composition: About 3 percent
Slope: 8 to 40 percent
Drainage class: Well drained
Ecological site: Clayey

Waumac and similar soils
Composition: About 2 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

354—Waumac Variant very gravelly sandy loam, 1 to 15 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,600 to 5,900 feet (1,707 to 1,798 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Waumac Variant and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Waumac Variant soils
Landscape: Uplands
Landform: Ridges, hills
Position on landform: Summits
Position on landform: Nose slope
Parent material: Residuum weathered from tuff
Slope: 1 to 15 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)

Available water capacity: About 0.7 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Apache plume, black grama, blue grama, broom snakeweed, little bluestem, sandhill muhly
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 3 inches; very gravelly sandy loam
C—3 to 12 inches; very gravelly sandy loam
Cr—12 to 60 inches; bedrock

Minor Components
Rock outcrop
Composition: About 10 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

358—Deama-Elpedro-Rock outcrop complex, 10 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,800 to 6,800 feet (1,768 to 2,073 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Deama and similar soils: 35 percent
Elpedro and similar soils: 25 percent
Rock outcrop: 25 percent
Minor components: 15 percent

Component Descriptions

Deama soils
Landscape: Uplands
Landform: Plateaus, hills, ridges, mesas
Position on landform: Shoulders
Position on landform: Side slope
Parent material: Colluvium over residuum weathered from limestone

Slope: 10 to 55 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 1.3 inches (very low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: About 60 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: twoneedle pinyon
Other plants: blue grama, sideoats grama, New Mexico Feathergrass
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 3 inches; very gravelly loam
Bk—3 to 19 inches; very gravelly loam
2R—19 to 60 inches; bedrock

Elpedro soils
Landscape: Uplands
Landform: Valley sides, mesas, hills, fan piedmonts, benches
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Eolian deposits over colluvium derived from limestone
Slope: 10 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 10.8 inches (high)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: High
Calcium carbonate maximum: About 15 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: blue grama, bottlebrush squirreltail, galleta, oak, western wheatgrass
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 3 inches; very gravelly loam
Bt—3 to 37 inches; silty clay loam
Btk—37 to 60 inches; loam

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Escarpments
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Minor Components
Espiritu and similar soils
Composition: About 10 percent
Slope: 15 to 40 percent
Drainage class: Well drained
Ecological site: Foothills

Menefee and similar soils
Composition: About 5 percent
Slope: 5 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

396—Atarque-Menefee-Rock outcrop complex, 25 to 45 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,000 to 6,600 feet (1,829 to 2,012 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Atarque and similar soils: 30 percent
Menefee and similar soils: 30 percent
Rock outcrop: 25 percent
Minor components: 15 percent

Component Descriptions

Atarque soils
Landscape: Uplands
Landform: Dipslopes, hills, mesas, cuestas
Position on landform: Shoulders
Position on landform: Nose slope
Parent material: Slope alluvium derived from sandstone and shale
Slope: 25 to 45 percent
Aspect: East to west
Shape (down/across): Linear/linear

Depth class: Very shallow and shallow
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 3.1 inches (low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Shallow Sandstone
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: sideoats grama, New Mexico Feathergrass, blue grama, little bluestem
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 2 inches; extremely gravelly sandy loam
Bt—2 to 16 inches; clay loam
R—16 to 60 inches; bedrock

Menefee soils
Landscape: Uplands
Landform: Hillslopes, mesas, mountainsides
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Colluvium over residuum weathered from shale
Slope: 25 to 45 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 8 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 2.7 inches (very low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis-Juniperus monosperma/Quercus gambelii/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Bigelow sagebrush, mormon tea, Indian ricegrass, Mexican cliffrose, bluegrass, galleta, green rabbitbrush
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 2 inches; gravelly clay loam
C—2 to 14 inches; clay loam
2Cr—14 to 60 inches; bedrock

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Hills, escarpments
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Minor Components
Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 8 percent
Drainage class: Well drained
Ecological site: Sandy

Flugle and similar soils
Composition: About 5 percent
Slope: 1 to 5 percent
Drainage class: Well drained
Ecological site: Savannah

Vessilla and similar soils
Composition: About 5 percent
Slope: 3 to 15 percent
Depth to restrictive feature: 6 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

397—Rock outcrop-Cucho-Vessilla complex, 25 to 70 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,000 to 7,200 feet (1,829 to 2,195 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Rock outcrop: 30 percent
Cucho and similar soils: 25 percent
Vessilla and similar soils: 25 percent
Minor components: 20 percent

Component Descriptions

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.

Landform: Hills, escarpments
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Cucho soils
Landscape: Uplands
Landform: Cuestas, fan remnants
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Colluvium derived from shale
Slope: 25 to 70 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 45 percent subrounded gravel
Depth class: Moderately deep
Depth to restrictive feature: 20 to 40 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 4.4 inches (low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: High
Calcium carbonate maximum: About 15 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Indian ricegrass, bottlebrush squirreltail, galleta, mountain mahogany, needle and thread, sideoats grama, skunkbush sumac, wavyleaf oak
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 2 inches; very gravelly clay loam
C1—2 to 9 inches; clay loam
C2—9 to 37 inches; very gravelly clay loam
Cr—37 to 60 inches; bedrock

Vessilla soils
Landscape: Uplands
Landform: Structural benches, hills, ridges, breaks, mesas
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Eolian material and alluvium derived from sandstone
Slope: 25 to 65 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 4 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)

Available water capacity: About 1.1 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: sideoats grama, New Mexico Feathergrass, blue grama, little bluestem, galleta
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 2 inches; gravelly fine sandy loam
C—2 to 11 inches; gravelly fine sandy loam
R—11 to 60 inches; bedrock

Minor Components
Atarque and similar soils
Composition: About 5 percent
Slope: 25 to 45 percent
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

Menefee and similar soils
Composition: About 5 percent
Slope: 25 to 45 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Skyvillage and similar soils
Composition: About 5 percent
Slope: 8 to 25 percent
Depth to restrictive feature: 6 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Shallow Sandstone

Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

398—Espiritu-Cucho association, 8 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,000 to 6,900 feet (1,829 to 2,103 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)

Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Espiritu and similar soils: 45 percent
Cucho and similar soils: 35 percent
Minor components: 20 percent

Component Descriptions

Espiritu soils
Landscape: Uplands
Landform: Mountain slopes, mesas
Position on landform: Backslopes
Position on landform: Mountainflank, lower third, side slope
Parent material: Slope alluvium and colluvium derived from igneous and sedimentary rock
Slope: 8 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 20 percent subrounded gravel
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 3.0 inches (very low)
Shrink-swell potential: About 2.6 percent (low)
Runoff class: High
Calcium carbonate maximum: About 1 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 2 (slightly sodic)
Ecological site: Foothills
Potential native vegetation: blue grama, hairy grama, black grama, sideoats grama, New Mexico Feathergrass, galleta, oneseed juniper, sacahuista
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 4 inches; very gravelly fine sandy loam
Bt—4 to 24 inches; very gravelly sandy clay loam
Bk—24 to 60 inches; extremely gravelly sandy loam

Cucho soils
Landscape: Uplands
Landform: Cuestas, fan remnants
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Colluvium derived from shale
Slope: 15 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Moderately deep
Depth to restrictive feature: 20 to 40 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 7.2 inches (moderate)

Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: High
Calcium carbonate maximum: About 15 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Indian ricegrass, bottlebrush squirreltail, galleta, mountain mahogany, needle and thread, sideoats grama, skunkbush sumac, wavyleaf oak
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 2 inches; very gravelly clay loam
C—2 to 37 inches; silty clay loam
Cr—37 to 60 inches; bedrock

Minor Components
Menefee and similar soils
Composition: About 10 percent
Slope: 5 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: Shallow

Waumac and similar soils
Composition: About 5 percent
Slope: 1 to 7 percent
Drainage class: Well drained
Ecological site: Sandy

Rock outcrop
Composition: About 5 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

399—Cucho-Teco complex, 8 to 40 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,900 to 7,000 feet (1,798 to 2,134 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Cucho and similar soils: 45 percent
Teco and similar soils: 35 percent
Minor components: 20 percent

Component Descriptions

Cucho soils
Landscape: Uplands
Landform: Cuestas, fan remnants
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Colluvium derived from shale
Slope: 15 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 50 percent subrounded gravel
Depth class: Moderately deep
Depth to restrictive feature: 20 to 40 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 7.2 inches (moderate)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: High
Calcium carbonate maximum: About 15 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Indian ricegrass, bottlebrush squirreltail, galleta, mountain mahogany, needle and thread, sideoats grama, skunkbush sumac, wavyleaf oak
Land capability subclass (nonirrigated): 6e

Typical Profile:
A—0 to 2 inches; very gravelly clay loam
C—2 to 37 inches; clay loam
Cr—37 to 60 inches; bedrock

Teco soils
Landscape: Uplands
Landform: Hills, cuestas
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Slope alluvium derived from sandstone and shale
Slope: 8 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: .06 to 0.2 in./hr. (slow)
Available water capacity: About 7.7 inches (moderate)
Shrink-swell potential: About 6.2 percent (high)
Runoff class: Very high
Calcium carbonate maximum: About 13 percent
Gypsum maximum: None
Salinity maximum: About 8 mmhos/cm (slightly saline)

Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Clayey
Potential native vegetation: alkali sacaton, western wheatgrass, New Mexico Feathergrass, blue grama, galleta, fourwing saltbush, winterfat
Land capability subclass (nonirrigated): 6e

Typical Profile:
A—0 to 1 inch; very cobbly fine sandy loam
Bt1—1 inch to 7 inches; sandy clay
Bt2—7 to 23 inches; clay
Btk—23 to 40 inches; clay
2C—40 to 45 inches; very gravelly fine sandy loam
3Bkb—45 to 60 inches; channery sandy clay loam

Minor Components
Espiritu and similar soils
Composition: About 10 percent
Slope: 15 to 40 percent
Drainage class: Well drained
Ecological site: Foothills

Menefee and similar soils
Composition: About 5 percent
Slope: 5 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Rock outcrop
Composition: About 5 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

405—Charo complex, 1 to 5 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 8,100 to 8,300 feet (2,469 to 2,530 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Charo and similar soils: 50 percent
Charo, noncobbly, and similar soils: 40 percent
Minor components: 10 percent

Component Descriptions

Charo soils
Landscape: Mountains
Landform: Mesas, ridges, hills
Position on landform: Shoulders
Position on landform: Crest, mountaintop
Parent material: Eolian deposits over residuum weathered from basalt

Slope: 1 to 5 percent
Aspect: East to west
Shape (down/across): Convex/linear
Surface fragments: About 2 percent subrounded stones
Depth class: Moderately deep
Depth to restrictive feature: 20 to 40 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: .06 to 0.2 in./hr. (slow)
Available water capacity: About 4.0 inches (low)
Shrink-swell potential: About 7.4 percent (high)
Runoff class: Medium
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa-Juniperus deppeana/Quercus gambelii
Potential native vegetation:
Common trees: Rocky Mountain juniper, twoneedle pinyon, ponderosa pine
Other plants: blue grama, Arizona fescue, mountain muhly, spineless horsebrush, Fendler ceanothus, prairie junegrass
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 5 inches; cobbly loam
Bt1—5 to 12 inches; clay
Bt2—12 to 15 inches; clay
Bt3—15 to 25 inches; clay
C—25 to 28 inches; clay
R—28 to 60 inches; bedrock

Charo, noncobbly soils
Landscape: Mountains
Landform: Hills, ridges, mesas
Position on landform: Shoulders
Position on landform: Crest, mountaintop
Parent material: Eolian deposits over residuum weathered from basalt
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Moderately deep
Depth to restrictive feature: 20 to 40 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: .06 to 0.2 in./hr. (slow)
Available water capacity: About 6.5 inches (moderate)
Shrink-swell potential: About 4.2 percent (moderate)
Runoff class: Medium
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Mountain Grassland
Potential native vegetation: Arizona fescue, mountain muhly, muttongrass, prairie junegrass
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 8 inches; loam
Bt—8 to 38 inches; clay
R—38 to 60 inches; bedrock

Minor Components
Rock outcrop
Composition: About 10 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

409—Santa Fe very gravelly sandy loam, 15 to 40 percent slopes, stony

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,800 to 7,600 feet (2,073 to 2,316 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Santa Fe and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Santa Fe soils
Landscape: Mountains
Landform: Mountain slopes
Position on landform: Backslopes
Position on landform: Mountainflank
Parent material: Slope alluvium over residuum weathered from granite
Slope: 15 to 40 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 0.5 inches (very low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: sideoats grama, blue grama, galleta, pinyon ricegrass
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 3 inches; very gravelly sandy loam
Bt—3 to 8 inches; very gravelly sandy clay loam
2R—8 to 60 inches; bedrock

Minor Components
Rock outcrop
Composition: About 10 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)
Ecological site: pinyon-juniper forest

Vessilla and similar soils
Composition: About 3 percent
Slope: 5 to 40 percent
Depth to restrictive feature: 6 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Waumac and similar soils
Composition: About 2 percent
Slope: 5 to 20 percent
Drainage class: Well drained
Ecological site: Sandy

410—Zia loam, 0 to 1 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Map Unit Composition

Zia and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Zia soils
Landscape: Valleys
Landform: Stream terraces
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Eolian deposits over stream alluvium derived from sandstone
Slope: 0 to 1 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 8.1 inches (moderate)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low

Calcium carbonate maximum: About 15 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Loamy
Potential native vegetation: blue grama, spike muhly, western wheatgrass, bottlebrush squirreltail, fourwing saltbush, oneseed juniper, winterfat
Land capability subclass (irrigated): 3e
Land capability subclass (nonirrigated): 6c

Typical Profile:
A—0 to 10 inches; loam
C—10 to 60 inches; stratified sandy loam to fine sandy loam

Minor Components
Pinavetes and similar soils
Composition: About 10 percent
Landform: Dunes, valley sides
Slope: 1 to 3 percent
Aspect: East to west
Drainage class: Excessively drained
Ecological site: Deep Sand

El Rancho and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Well drained
Ecological site: Loamy

414—Wauquie very gravelly fine sandy loam, 8 to 25 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,400 to 6,700 feet (1,951 to 2,042 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Wauquie and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Wauquie soils
Landscape: Uplands
Landform: Mesas, canyons, fan piedmonts, benches, hills
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Slope alluvium over colluvium derived from igneous and sedimentary rock

Slope: 8 to 25 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 3.6 inches (low)
Shrink-swell potential: About 2.9 percent (low)
Runoff class: Medium
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Eriogonum, blue grama, skunkbush sumac, slender wheatgrass, bottlebrush squirreltail, wavyleaf oak
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 3 inches; very gravelly fine sandy loam
Bt—3 to 30 inches; very gravelly sandy clay loam
Bk—30 to 60 inches; stratified very gravelly sandy loam to very gravelly loamy coarse sand

Minor Components

Santa Fe and similar soils
Composition: About 5 percent
Slope: 15 to 40 percent
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Bamac and similar soils
Composition: About 5 percent
Slope: 15 to 55 percent
Drainage class: Excessively drained
Ecological site: Foothills

Laventana and similar soils
Composition: About 5 percent
Slope: 3 to 15 percent
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

417—Jocity loam, 0 to 2 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,300 to 5,500 feet (1,615 to 1,676 meters)

Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Jocity and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Jocity soils
Landscape: Valleys
Landform: Alluvial fans, flood plains
Position on landform: Toeslopes
Position on landform: Rise, base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 0 to 2 percent
    Aspect: East to west
    Shape (down/across): Linear, concave/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 9.6 inches (high)
Shrink-swell potential: About 4.0 percent (moderate)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 2e
Land capability subclass (nonirrigated): 7c

Typical Profile:
    Ap—0 to 10 inches; loam
    C1—10 to 26 inches; silty clay loam
    C2—26 to 32 inches; loam
    C3—32 to 50 inches; sandy clay loam
    C4—50 to 56 inches; sandy loam
    C5—56 to 60 inches; loamy sand

Minor Components
Zia and similar soils
    Composition: About 5 percent
    Slope: 1 to 3 percent
    Drainage class: Well drained
    Ecological site: Sandy

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Sparham and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

418—Jocity clay loam, 0 to 2 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,300 to 5,600 feet (1,615 to 1,707 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Jocity and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Jocity soils
Landscape: Valleys
Landform: Alluvial fans, flood plains
Position on landform: Toeslopes
Position on landform: Base slope, rise
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 0 to 2 percent
Aspect: East to west
Shape (down/across): Concave, linear/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 8.6 inches (moderate)
Shrink-swell potential: About 2.9 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 2e
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 12 inches; clay loam
C1—12 to 30 inches; clay loam
C2—30 to 60 inches; stratified loamy sand to sandy loam

Minor Components
Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Sparham and similar soils
Composition: About 3 percent
Slope: 0 to 1 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

Zia and similar soils
Composition: About 2 percent
Slope: 1 to 4 percent
Drainage class: Well drained
Ecological site: Sandy

419—Santa Fe-Wauquie-Rock outcrop complex, 25 to 70 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,400 to 8,400 feet (1,951 to 2,560 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Santa Fe and similar soils: 40 percent
Wauquie and similar soils: 30 percent
Rock outcrop: 20 percent
Minor components: 10 percent

Component Descriptions

Santa Fe soils
Landscape: Mountains
Landform: Mountain slopes

Position on landform: Backslopes, mountainflanks
Parent material: Slope alluvium over residuum weathered from granite
Slope: 25 to 70 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 8 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 0.8 inches (very low)
Shrink-swell potential: About 3.2 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: sideoats grama, blue grama, galleta, pinyon ricegrass
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 9 inches; extremely cobbly coarse sandy loam
Bt—9 to 16 inches; very gravelly sandy clay loam
2R—16 to 60 inches; bedrock

Wauquie soils
Landscape: Mountains
Landform: Benches, mountain slopes, canyons, hills, mesas
Position on landform: Footslopes
Position on landform: Mountainflank
Parent material: Slope alluvium over residuum weathered from granite
Slope: 25 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 1.4 inches (very low)
Shrink-swell potential: About 2.3 percent (low)
Runoff class: High
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Juniperus monosperma-Pinus edulis/Fallugia paradoxa-Chrysothamnus nauseosus/Bouteloua hirsuta-Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: skunkbush sumac, Gambel oak, bluegrass, bottlebrush squirreltail, mountain big sagebrush, mountain mahogany, mountain muhly, pine dropseed, pinyon ricegrass, prairie junegrass
Land capability subclass (nonirrigated): 7e

Typical Profile:
A—0 to 4 inches; extremely cobbly fine sandy loam
Bt1—4 to 11 inches; extremely cobbly sandy clay loam
Bt2—11 to 18 inches; extremely cobbly sandy clay loam
Bt3—18 to 29 inches; extremely cobbly sandy loam
Bk—29 to 60 inches; extremely cobbly sand

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Escarpments, hills
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Minor Components
Osha and similar soils
Composition: About 10 percent
Slope: 35 to 55 percent
Drainage class: Somewhat excessively drained
Ecological site: Pinus ponderosa/Quercus gambelii

420—Pinavetes loamy sand, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 5,200 to 6,000 feet (1,585 to 1,829 meters)
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Map Unit Composition

Pinavetes and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Pinavetes soils
Landscape: Uplands
Landform: Dunes, valley sides
Position on landform: Shoulders
Position on landform: Side slope
Parent material: Eolian sands derived from sandstone
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Convex/convex
Depth class: Very deep
Drainage class: Excessively drained
Slowest permeability: 6.0 to 20 in./hr. (rapid)
Available water capacity: About 2.7 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very low
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None

Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Deep Sand
Potential native vegetation: Indian ricegrass, blue grama, sand sagebrush
Land capability subclass (irrigated): 3s
Land capability subclass (nonirrigated): 6c

Typical Profile:
A—0 to 10 inches; loamy sand
C—10 to 60 inches; sand

Minor Components
Zia and similar soils
Composition: About 5 percent
Slope: 5 to 20 percent
Drainage class: Well drained
Ecological site: Sandy

El Rancho and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Well drained
Ecological site: Loamy

Pinavetes and similar soils
Composition: About 5 percent
Slope: 5 to 15 percent
Drainage class: Excessively drained
Ecological site: Deep Sand

421—Gilco loam, moderately saline, sodic, 0 to 1 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,100 to 5,500 feet (1,554 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Gilco, moderately saline, sodic and similar soils: 90 percent
Minor components: 10 percent

Component Descriptions

Gilco, moderately saline, sodic soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock

Slope: 0 to 1 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 9.0 inches (high)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 16 mmhos/cm (moderately saline)
Sodium adsorption ratio maximum: About 30 (strongly sodic)
Ecological site: Salty Bottomland
Potential native vegetation: alkali sacaton, galleta, bottlebrush squirreltail, fourwing saltbush, greasewood
Land capability subclass (irrigated): 4s
Land capability subclass (nonirrigated): 7c

Typical Profile:
Ap—0 to 7 inches; loam
C1—7 to 19 inches; very fine sandy loam
C2—19 to 60 inches; stratified fine sandy loam to loam

Minor Components

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Jocity and similar soils
Composition: About 3 percent
Slope: 0 to 2 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Peralta and similar soils
Composition: About 2 percent
Slope: 0 to 2 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

422—Vessilla-Menefee-Orlie association, 0 to 30 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,100 to 7,200 feet (1,859 to 2,195 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Vessilla and similar soils: 35 percent
Menefee and similar soils: 30 percent
Orlie and similar soils: 25 percent
Minor components: 10 percent

Component Descriptions

Vessilla soils
Landscape: Uplands
Landform: Ridges, breaks, mesas, hills
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Eolian deposits over slope alluvium over residuum weathered from sandstone
Slope: 5 to 30 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 4 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 1.8 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis/Rhus trilobata/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: Indian ricegrass, blue grama, mountain big sagebrush, oak, galleta, sideoats grama
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 1 inch; sandy loam
C—1 inch to 15 inches; sandy loam
R—15 to 60 inches; bedrock

Menefee soils
Landscape: Uplands
Landform: Hillslopes, mesas, mountainsides

Position on landform: Backslopes
Position on landform: Side slope
Parent material: Colluvium over residuum weathered from shale
Slope: 2 to 9 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very shallow and shallow
Depth to restrictive feature: 8 to 20 inches to bedrock (paralithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 2.0 inches (very low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: About 15 percent
Gypsum maximum: About 1 percent
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus edulis-Juniperus monosperma/Quercus gambelii/Bouteloua gracilis
Potential native vegetation:
Common trees: Rocky Mountain juniper, oneseed juniper, twoneedle pinyon
Other plants: blue grama, galleta, Gambel oak, big sagebrush, sideoats grama
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 3 inches; clay loam
C—3 to 10 inches; clay loam
2Cr—10 to 60 inches; bedrock

Orlie soils
Landscape: Uplands
Landform: Mesas, valley sides, hills, cuestas
Position on landform: Footslopes
Position on landform: Side slope
Parent material: Eolian material and alluvium derived from sandstone and shale
Slope: 0 to 8 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 11.7 inches (high)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 2 (slightly sodic)
Ecological site: Loamy
Potential native vegetation: western wheatgrass, big sagebrush, galleta, Indian ricegrass, needle and thread, fourwing saltbush
Land capability subclass (nonirrigated): 6c

Typical Profile:
A—0 to 4 inches; loam
Bt—4 to 14 inches; silty clay loam
C—14 to 60 inches; silty clay loam

Minor Components
Sparank and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Well drained
Flooding hazard: Occasional
Ecological site: Clayey Bottomland

Rock outcrop
Composition: About 5 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

423—Gilco loam, 1 to 4 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,300 to 5,500 feet (1,615 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Gilco and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Gilco soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 4 percent
Aspect: East to west
Shape (down/across): Concave/linear
Surface fragments: About 12 percent subrounded gravel
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 9.6 inches (high)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)

Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 4e
Land capability subclass (nonirrigated): 7e

Typical Profile:
Ap—0 to 8 inches; loam
C1—8 to 14 inches; loam
C2—14 to 60 inches; stratified fine sandy loam to silt loam

Minor Components
Peralta and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

Jocity and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

426—Aga loam, moderately saline, sodic, 0 to 1 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Aga, moderately saline, sodic and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Aga, moderately saline, sodic soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock

Slope: 0 to 1 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 5.0 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 16 mmhos/cm (moderately saline)
Sodium adsorption ratio maximum: About 30 (strongly sodic)
Ecological site: Bottomland
Potential native vegetation: alkali sacaton, fourwing saltbush, giant sacaton, inland saltgrass, greasewood
Land capability subclass (irrigated): 4s
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 8 inches; loam
C1—8 to 20 inches; loam
2C2—20 to 36 inches; loamy sand
2C3—36 to 60 inches; gravelly sand

Minor Components
Gilco and similar soils
Composition: About 10 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Peralta and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

427—Aga loam, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Aga and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Aga soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 7.6 inches (moderate)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 42 to 60 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 2e
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 8 inches; loam
C1—8 to 28 inches; loam
2C2—28 to 60 inches; loamy fine sand

Minor Components
Gilco and similar soils
Composition: About 10 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Jocity and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

428—Aga loam, moderately saline, sodic, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,200 to 5,500 feet (1,585 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Aga, moderately saline, sodic and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Aga, moderately saline, sodic soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 5.5 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 16 mmhos/cm (moderately saline)
Sodium adsorption ratio maximum: About 30 (strongly sodic)
Ecological site: Salty Bottomland
Potential native vegetation: alkali sacaton, fourwing saltbush, giant sacaton, inland saltgrass, greasewood
Land capability subclass (irrigated): 4s
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 4 inches; loam
C1—4 to 16 inches; very fine sandy loam
2C2—16 to 22 inches; loam
2C3—22 to 60 inches; stratified sand to loamy sand

Minor Components

Peralta and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Jocity and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

430—Trail loam, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Trail and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Trail soils

Landscape: Valleys
Landform: Flood plains, valley floor remnants, channels, alluvial fans
Position on landform: Toeslopes
Position on landform: Rise, base slope
Parent material: Eolian deposits over stream alluvium derived from sandstone
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Somewhat excessively drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 4.4 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Runoff class: Very low
Calcium carbonate maximum: About 5 percent

Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Bottomland
Potential native vegetation: alkali sacaton, giant sacaton, fourwing saltbush
Land capability subclass (irrigated): 4e
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 10 inches; loam
C1—10 to 34 inches; loamy sand
C2—34 to 60 inches; stratified sand to fine sandy loam

Minor Components
Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Peralta and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

431—Trail loamy sand, 1 to 4 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Trail and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Trail soils
Landscape: Valleys
Landform: Valley floor remnants, flood plains, channels, alluvial fans
Position on landform: Toeslopes

Position on landform: Base slope, rise
Parent material: Eolian deposits over stream alluvium derived from sandstone
Slope: 1 to 4 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 5.1 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Runoff class: Very low
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Deep Sand
Potential native vegetation: Indian ricegrass, black grama, sand sagebrush, dropseed
Land capability subclass (irrigated): 4e
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 10 inches; loamy sand
C—10 to 60 inches; stratified loamy sand to sand to gravelly sand to fine sandy loam

Minor Components
El Rancho and similar soils
Composition: About 5 percent
Slope: 0 to 2 percent
Drainage class: Well drained
Ecological site: Loamy

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Riverwash
Composition: About 3 percent
Landscape: Valleys
Landform: Streams, channels
Position on landform: Toeslopes
Position on landform: Base slope
Slope: 0 to 3 percent
Shape (down/across): Concave/linear
Drainage class: Somewhat poorly drained
Flooding hazard: Frequent

Zia and similar soils
Composition: About 2 percent
Slope: 1 to 9 percent
Drainage class: Well drained
Ecological site: Sandy

433—Peralta loam, 0 to 1 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Peralta and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Peralta soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 0 to 1 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Somewhat poorly drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 8.6 inches (moderate)
Shrink-swell potential: About 1.8 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 24 to 36 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 8 mmhos/cm (slightly saline)
Sodium adsorption ratio maximum: About 13 (moderately sodic)
Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 3e
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 10 inches; loam
C—10 to 60 inches; stratified very fine sandy loam to fine sandy loam to loamy fine sand

Minor Components

Aga and similar soils
Composition: About 10 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

434—Peralta loam, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,400 feet (1,524 to 1,646 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Peralta and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Peralta soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes, base slopes
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Somewhat poorly drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 7.8 inches (moderate)
Shrink-swell potential: About 2.3 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 24 to 36 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 8 mmhos/cm (slightly saline)
Sodium adsorption ratio maximum: About 13 (moderately sodic)
Ecological site: Bottomland
Potential native vegetation: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 3e
Land capability subclass (nonirrigated): 7c

Typical Profile:
Ap—0 to 10 inches; loam
C1—10 to 16 inches; very fine sandy loam
C2—16 to 20 inches; clay loam
C3—20 to 28 inches; fine sandy loam
C4—28 to 40 inches; loamy sand
C5—40 to 45 inches; silt loam
C6—45 to 60 inches; loamy fine sand

Minor Components
Aga and similar soils
Composition: About 10 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

437—Peralta loam, moderately saline, sodic, 1 to 3 percent slopes

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,400 feet (1,524 to 1,646 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Peralta, moderately saline, sodic and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Peralta, moderately saline, sodic soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 3 percent
Aspect: East to west
Shape (down/across): Concave/linear
Depth class: Very deep
Drainage class: Somewhat poorly drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 8.4 inches (moderate)
Shrink-swell potential: About 1.5 percent (low)

Flooding hazard: Rare
Seasonal high water table depth: About 24 to 36 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 16 mmhos/cm (moderately saline)
Sodium adsorption ratio maximum: About 30 (strongly sodic)
Ecological site: Salty Bottomland
Potential native vegetation: alkali sacaton, fourwing saltbush, giant sacaton, inland saltgrass, greasewood
Land capability subclass (irrigated): 4s
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 4 inches; loam
C—4 to 60 inches; stratified loam to fine sandy loam to loamy sand

Minor Components
Aga and similar soils
Composition: About 10 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Gilco and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

500—Rock outcrop-Osha-Rubble land complex, 40 to 70 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 7,000 to 9,000 feet (2,134 to 2,743 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Rock outcrop: 40 percent
Osha and similar soils: 30 percent
Rubble land: 20 percent
Minor components: 10 percent

Component Descriptions

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.

Landform: Ledges, escarpments, benches
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Osha soils
Landscape: Mountains
Landform: Mountain slopes, ridges
Position on landform: Backslopes
Position on landform: Mountainflank, crest
Parent material: Colluvium over residuum weathered from granite
Slope: 40 to 70 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Deep
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Somewhat excessively drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 1.4 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Medium
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Gambel oak, blue grama, New Mexico locust, Rocky Mountain juniper, mountain muhly, prairie junegrass, skunkbush sumac, wavyleaf oak
Land capability subclass (nonirrigated): 7c

Typical Profile:
AB—0 to 10 inches; very gravelly coarse sandy loam
Bw—10 to 20 inches; very gravelly coarse sandy loam
Ct—20 to 43 inches; extremely gravelly loamy coarse sand
R—43 to 60 inches; bedrock

Rubble land
Description: Rubble land consists of areas with 90 percent or more of the surface covered with cobbles, stones, and boulders.
Landform: Hills
Position on landform: Side slope
Slope: 40 to 70 percent
Aspect: East to west
Drainage class: Excessively drained
Available water capacity: About 0.6 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 0 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Land capability subclass (nonirrigated): 8s

Minor Components

Cypher and similar soils
Composition: About 5 percent
Slope: 15 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Palon and similar soils
Composition: About 5 percent
Slope: 15 to 35 percent
Drainage class: Well drained
Ecological site: Pseudotsuga menziesii-Pinus ponderosa/Muhlenbergia

503—Cajete-Cypher association, 8 to 50 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 7,000 to 7,300 feet (2,134 to 2,225 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Cajete and similar soils: 65 percent
Cypher and similar soils: 25 percent
Minor components: 10 percent

Component Descriptions

Cajete soils

Landscape: Mountains
Landform: Hills, mountain slopes
Position on landform: Backslopes
Position on landform: Mountainflank, upper third, crest
Parent material: Residuum weathered from pumice
Slope: 8 to 30 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 3.3 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low
Calcium carbonate maximum: About 5 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii

Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, Kentucky bluegrass, Thurber fescue, bluegrass, common juniper, mountain muhly, needlegrass, pine dropseed, sedge, western wheatgrass
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 8 inches; extremely gravelly coarse sandy loam
C—8 to 60 inches; very gravelly sandy loam

Cypher soils
Landscape: Mountains
Landform: Ridges, mountain slopes
Position on landform: Backslopes
Position on landform: Mountainflank
Parent material: Colluvium derived from tuff over residuum weathered from rhyolite
Slope: 30 to 50 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 2 percent subrounded cobbles
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 0.8 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, little bluestem, mountain muhly, California brome, big bluestem, sideoats grama
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 3 inches; very gravelly loam
BC1—3 to 11 inches; very gravelly sandy loam
BC2—11 to 15 inches; extremely gravelly sandy loam
2R—15 to 60 inches; bedrock

Minor Components
Laventana and similar soils
Composition: About 5 percent
Slope: 3 to 15 percent
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: ponderosa forest

Mirand and similar soils
Composition: About 3 percent
Slope: 5 to 30 percent
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Rock outcrop
Composition: About 2 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

504—Orejas-Guaje complex, 1 to 15 percent slopes

Map Unit Setting

Major Land Resource Area: 36
Elevation: 6,000 to 7,000 feet (1,829 to 2,134 meters)
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (8.9 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Map Unit Composition

Orejas and similar soils: 40 percent
Guaje and similar soils: 35 percent
Minor components: 25 percent

Component Descriptions

Orejas soils
Landscape: Uplands
Landform: Plateaus, mesas
Position on landform: Summits
Position on landform: Side slope
Parent material: Eolian material, slope alluvium and colluvium derived from basalt
Slope: 5 to 15 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.2 to 0.6 in./hr. (moderately slow)
Available water capacity: About 1.7 inches (very low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: Very high
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Pinus edulis-Juniperus monosperma/Quercus gambelii/Bouteloua gracilis
Potential native vegetation:
Common trees: twoneedle pinyon, oneseed juniper
Other plants: big sagebrush, blue grama, sideoats grama
Land capability subclass (nonirrigated): 7s

Typical Profile:
A—0 to 2 inches; very cobbly loam
Bt—2 to 9 inches; very cobbly clay loam
C—9 to 17 inches; very gravelly clay loam
R—17 to 60 inches; bedrock

Guaje soils
Landscape: Uplands
Landform: Hills, volcanic cones
Position on landform: Backslopes
Position on landform: Side slope
Parent material: Eolian material and alluvium derived from volcanic rock
Slope: 1 to 8 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 20 percent subrounded gravel
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 3.1 inches (low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low
Calcium carbonate maximum: About 20 percent
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Pinus edulis-Juniperus monosperma/Quercus gambelii/Bouteloua gracilis
Potential native vegetation:
Common trees: oneseed juniper, twoneedle pinyon
Other plants: blue grama, galleta, sideoats grama, New Mexico Feathergrass, little bluestem, mountain muhly, pine dropseed, sand dropseed
Land capability subclass (nonirrigated): 6s

Typical Profile:
A—0 to 4 inches; gravelly sandy loam
Bw—4 to 12 inches; gravelly sandy loam
Bk1—12 to 17 inches; very gravelly sandy loam
Bk2—17 to 45 inches; extremely gravelly sandy loam
Bk3—45 to 60 inches; very gravelly sandy loam

Minor Components
Elpedro and similar soils
Composition: About 10 percent
Slope: 1 to 8 percent
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Guaje, very cobbly and similar soils
Composition: About 10 percent
Slope: 1 to 8 percent
Drainage class: Well drained
Ecological site: pinyon-juniper forest

Orejas, steep and similar soils
Composition: About 5 percent
Slope: 15 to 40 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: pinyon-juniper forest

600—Rock outcrop-Cypher complex, 35 to 60 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 6,500 to 7,400 feet (1,981 to 2,256 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Rock outcrop: 50 percent
Cypher and similar soils: 35 percent
Minor components: 15 percent

Component Descriptions

Rock outcrop
Description: Rock outcrop consists of barren or nearly barren areas of bedrock as benches, ledges, and escarpments.
Landform: Mountain slopes, scarps
Aspect: East to west
Depth to restrictive feature: 0 inches to bedrock (lithic)
Land capability subclass (nonirrigated): 8s

Cypher soils
Landscape: Mountains
Landform: Mountain slopes, ridges
Position on landform: Backslopes, mountainflanks
Parent material: Colluvium and residuum weathered from tuff and/or colluvium and residuum weathered from rhyolite
Slope: 35 to 60 percent
Aspect: East to west
Shape (down/across): Linear/linear
Surface fragments: About 3 percent subrounded gravel
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 1.5 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Very high
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii

Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, California brome, little bluestem, mountain muhly
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 4 inches; very cobbly loam
BC1—4 to 14 inches; very gravelly loam
BC2—14 to 16 inches; very gravelly loam
2R—16 to 60 inches; bedrock

Minor Components
Cypher and similar soils
Composition: About 5 percent
Slope: 15 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Cajete and similar soils
Composition: About 5 percent
Slope: 8 to 30 percent
Drainage class: Well drained
Ecological site: Mountain Grassland

Laventana and similar soils
Composition: About 3 percent
Slope: 3 to 15 percent
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Rock outcrop
Composition: About 2 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

601—Laventana gravelly sandy loam, 3 to 15 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 7,400 to 7,600 feet (2,256 to 2,316 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Laventana and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Laventana soils
Landscape: Mountains
Landform: Pediments, mountain slopes
Position on landform: Footslopes
Position on landform: Mountainflank
Parent material: Colluvium derived from granite and/or colluvium derived from andesite
Slope: 3 to 15 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Deep
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 4.1 inches (low)
Shrink-swell potential: About 4.4 percent (moderate)
Runoff class: Medium
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Gambel oak, mountain mahogany, bottlebrush squirreltail, prairie junegrass, sedge
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 5 inches; gravelly sandy loam
E—5 to 9 inches; very gravelly loam
Bt—9 to 50 inches; very gravelly sandy clay loam
2R—50 to 60 inches; bedrock

Minor Components
Mirand and similar soils
Composition: About 10 percent
Slope: 5 to 30 percent
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Rock outcrop
Composition: About 5 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

603—Laventana-Mirand very cobbly loams, 15 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 7,000 to 8,900 feet (2,134 to 2,713 meters)

Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Laventana and similar soils: 50 percent
Mirand and similar soils: 35 percent
Minor components: 15 percent

Component Descriptions

Laventana soils
Landscape: Mountains
Landform: Pediments, mountain slopes
Position on landform: Footslopes
Position on landform: Mountainflank
Parent material: Colluvium derived from granite and/or colluvium derived from andesite
Slope: 20 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Deep
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 4.8 inches (low)
Shrink-swell potential: About 4.5 percent (moderate)
Runoff class: High
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Gambel oak, mountain mahogany, bottlebrush squirreltail, prairie junegrass, sedge
Land capability subclass (nonirrigated): 7c

Typical Profile:
Oi—0 to 1 inch; slightly decomposed plant material
A—1 inch to 5 inches; very cobbly loam
E—5 to 12 inches; gravelly silt loam
Bt1—12 to 20 inches; very cobbly loam
Bt2—20 to 31 inches; very gravelly loam
Bt3—31 to 51 inches; very gravelly loam
2R—51 to 60 inches; bedrock

Mirand soils
Landscape: Mountains
Landform: Mountain slopes
Position on landform: Toeslopes
Position on landform: Mountainflank
Parent material: Colluvium derived from rhyolite and/or colluvium derived from tuff

Slope: 15 to 25 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: .06 to 0.2 in./hr. (slow)
Available water capacity: About 8.0 inches (moderate)
Shrink-swell potential: About 7.4 percent (high)
Runoff class: Very high
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, mountain muhly, prairie junegrass, California brome, Gambel oak, bottlebrush squirreltail, muttongrass, pine dropseed
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 6 inches; very cobbly loam
Bt1—6 to 27 inches; cobbly clay
Bt2—27 to 60 inches; sandy clay

Minor Components

Cypher and similar soils
Composition: About 5 percent
Slope: 15 to 35 percent
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Cajete and similar soils
Composition: About 5 percent
Slope: 8 to 30 percent
Drainage class: Well drained
Ecological site: Mountain Grassland

Rock outcrop
Composition: About 3 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

Totavi and similar soils
Composition: About 2 percent
Slope: 0 to 5 percent
Drainage class: Well drained
Flooding hazard: Rare
Ecological site: Pinus ponderosa-Juniperus deppeana/Quercus gambelii

604—Cypher-Mirand complex, 15 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 6,900 to 9,000 feet (2,103 to 2,743 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Cypher and similar soils: 55 percent
Mirand and similar soils: 30 percent
Minor components: 15 percent

Component Descriptions

Cypher soils
Landscape: Mountains
Landform: Mountain slopes, ridges
Position on landform: Summits
Position on landform: Mountainflank
Parent material: Colluvium derived from tuff over residuum weathered from rhyolite
Slope: 15 to 35 percent
    Aspect: East to west
    Shape (down/across): Linear/linear
Surface fragments: About 10 percent subrounded gravel
Depth class: Shallow
Depth to restrictive feature: 10 to 20 inches to bedrock (lithic)
Drainage class: Well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 1.5 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: High
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
    Common trees: ponderosa pine
    Other plants: Arizona fescue, little bluestem, mountain muhly, California brome, big bluestem, sideoats grama
Land capability subclass (nonirrigated): 7c

Typical Profile:
    Oi—0 to 1 inch; slightly decomposed plant material
    A—1 inch to 4 inches; very gravelly loam
    BCw—4 to 11 inches; very gravelly loam
    C—11 to 19 inches; extremely gravelly sandy loam
    2R—19 to 60 inches; bedrock

Mirand soils
Landscape: Mountains
Landform: Mountain slopes

Position on landform: Toeslopes
Position on landform: Mountainflank
Parent material: Colluvium derived from rhyolite and/or colluvium derived from tuff
Slope: 15 to 55 percent
Aspect: East to west
Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Well drained
Slowest permeability: .06 to 0.2 in./hr. (slow)
Available water capacity: About 6.4 inches (moderate)
Shrink-swell potential: About 7.5 percent (high)
Runoff class: High
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, mountain muhly, California brome, Gambel oak, bottlebrush squirreltail, muttongrass, pine dropseed, prairie junegrass
Land capability subclass (nonirrigated): 7c

Typical Profile:
A—0 to 4 inches; very cobbly loam
Bt—4 to 60 inches; cobbly clay

Minor Components
Alanos and similar soils
Composition: About 5 percent
Slope: 20 to 40 percent
Drainage class: Well drained
Ecological site: Pseudotsuga menziesii-Pinus ponderosa/Muhlenbergia

Laventana and similar soils
Composition: About 5 percent
Slope: 3 to 15 percent
Depth to restrictive feature: 40 to 60 inches to bedrock (lithic)
Drainage class: Well drained
Ecological site: Pinus ponderosa/Quercus gambelii

Rock outcrop
Composition: About 3 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

Totavi and similar soils
Composition: About 2 percent
Slope: 0 to 5 percent
Drainage class: Well drained
Flooding hazard: Rare
Ecological site: Pinus ponderosa-Juniperus deppeana/Quercus gambelii

608—Osha association, 3 to 55 percent slopes

Map Unit Setting

Major Land Resource Area: 48A
Elevation: 8,500 to 9,000 feet (2,591 to 2,743 meters)
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Map Unit Composition

Osha, steep and similar soils: 60 percent
Osha and similar soils: 30 percent
Minor components: 10 percent

Component Descriptions

Osha, steep soils
Landscape: Mountains
Landform: Mountain slopes, ridges
Position on landform: Backslopes
Position on landform: Mountainflank
Parent material: Colluvium over residuum weathered from granite
Slope: 35 to 55 percent
    Aspect: East to west
    Shape (down/across): Linear/linear
Depth class: Very deep
Drainage class: Somewhat excessively drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 1.8 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Medium
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
    Common trees: ponderosa pine
    Other plants: Arizona fescue, pine dropseed, prairie junegrass, Gambel oak, New Mexico locust, bluegrass, mountain muhly
Land capability subclass (nonirrigated): 7c

Typical Profile:
    A—0 to 3 inches; gravelly coarse sandy loam
    AB—3 to 8 inches; gravelly coarse sandy loam
    Bw—8 to 16 inches; gravelly coarse sandy loam
    Ct1—16 to 32 inches; extremely gravelly coarse sandy loam
    Ct2—32 to 60 inches; extremely gravelly loamy coarse sand

Osha soils
Landscape: Mountains
Landform: Ridges, mountain slopes
Position on landform: Shoulders
Position on landform: Mountainflank

Parent material: Colluvium and residuum weathered from granite
Slope: 3 to 35 percent
Aspect: East to west
Shape (down/across): Convex/linear
Depth class: Very deep
Drainage class: Somewhat excessively drained
Slowest permeability: 2.0 to 6.0 in./hr. (moderately rapid)
Available water capacity: About 2.2 inches (very low)
Shrink-swell potential: About 1.5 percent (low)
Runoff class: Low
Calcium carbonate maximum: None
Gypsum maximum: None
Salinity maximum: About 2 mmhos/cm (nonsaline)
Sodium adsorption ratio maximum: About 0 (nonsodic)
Ecological site: Pinus ponderosa/Quercus gambelii
Potential native vegetation:
Common trees: ponderosa pine
Other plants: Arizona fescue, Gambel oak, New Mexico locust, bluegrass, grouse whortleberry, mountain muhly, pine dropseed, prairie junegrass
Land capability subclass (nonirrigated): 7c

Typical Profile:
AB—0 to 8 inches; gravelly coarse sandy loam
Bw—8 to 16 inches; gravelly coarse sandy loam
Ct1—16 to 32 inches; extremely gravelly coarse sandy loam
Ct2—32 to 60 inches; extremely gravelly loamy coarse sand

Minor Components
Palon and similar soils
Composition: About 8 percent
Slope: 15 to 35 percent
Drainage class: Well drained
Ecological site: Pseudotsuga menziesii-Pinus ponderosa/Muhlenbergia

Rock outcrop
Composition: About 2 percent
Depth to restrictive feature: 0 inches to bedrock (lithic)

823—Gilco loam, 1 to 4 percent slopes, unprotected

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Map Unit Composition

Gilco, unprotected and similar soils: 85 percent
Minor components: 15 percent

Component Descriptions

Gilco, unprotected soils
Landscape: Valleys
Landform: Flood plains
Position on landform: Toeslopes
Position on landform: Base slope
Parent material: Stream alluvium derived from igneous and sedimentary rock
Slope: 1 to 4 percent
Aspect: East to west
Shape (down/across): Concave/linear
Surface fragments: About 12 percent subrounded medium and coarse gravel
Depth class: Very deep
Drainage class: Moderately well drained
Slowest permeability: 0.6 to 2.0 in./hr. (moderate)
Available water capacity: About 9.4 inches (high)
Shrink-swell potential: About 1.5 percent (low)
Flooding hazard: Rare
Seasonal high water table depth: About 48 to 72 inches
Runoff class: Low
Calcium carbonate maximum: About 10 percent
Gypsum maximum: None
Salinity maximum: About 4 mmhos/cm (very slightly saline)
Sodium adsorption ratio maximum: About 5 (slightly sodic)
Ecological site: Bottomland
Potential native vegetation:
Common trees: Rio Grande cottonwood
Other plants: giant sacaton, alkali sacaton, fourwing saltbush
Land capability subclass (irrigated): 4e
Land capability subclass (nonirrigated): 7e

Typical Profile:
Ap—0 to 8 inches; loam
C—8 to 60 inches; stratified fine sandy loam to loam to silt loam

Minor Components
Jocity and similar soils
Composition: About 6 percent
Slope: 0 to 2 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Aga and similar soils
Composition: About 5 percent
Slope: 0 to 1 percent
Drainage class: Moderately well drained
Flooding hazard: Rare
Ecological site: Bottomland

Peralta and similar soils
Composition: About 2 percent
Slope: 1 to 3 percent
Drainage class: Somewhat poorly drained
Flooding hazard: Rare
Ecological site: Bottomland

Trail and similar soils
Composition: About 2 percent
Slope: 1 to 3 percent
Drainage class: Somewhat excessively drained
Flooding hazard: Rare
Ecological site: Bottomland

827—Aga loam, 1 to 3 percent slopes, unprotected

Map Unit Setting

Major Land Resource Area: 42
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)

Use and Management of the Soils

This soil survey is an inventory and evaluation of the soils in the survey area. It can be used to adjust land uses to the limitations and potentials of natural resources and the environment. Also, it can help to prevent soil-related failures in land uses.

In preparing a soil survey, soil scientists, conservationists, engineers, and others collect extensive field data about the nature and behavioral characteristics of the soils. They collect data on erosion, droughtiness, flooding, and other factors that affect various soil uses and management. Field experience and collected data on soil properties and performance are used as a basis in predicting soil behavior.

Information in this section can be used to plan the use and management of soils for crops and pasture; as rangeland and forestland; as sites for buildings, sanitary facilities, highways and other transportation systems, and parks and other recreational facilities; for agricultural waste management; and as wildlife habitat. It can be used to identify the potentials and limitations of each soil for specific land uses and to help prevent construction failures caused by unfavorable soil properties.

Planners and others using soil survey information can evaluate the effect of specific land uses on productivity and on the environment in all or part of the survey area. The survey can help planners to maintain or create a land use pattern in harmony with the natural soil.

Contractors can use this survey to locate sources of sand and gravel, roadfill, and topsoil. They can use it to identify areas where bedrock, wetness, or very firm soil layers can cause difficulty in excavation.

Health officials, highway officials, engineers, and others may also find this survey useful. The survey can help them plan the safe disposal of wastes and locate sites for pavements, sidewalks, campgrounds, playgrounds, lawns, and trees and shrubs.

Interpretive Ratings

The interpretive tables in this survey rate the soils in the survey area for various uses. Many of the tables identify the limitations that affect specified uses and indicate the severity of those limitations. The ratings in these tables are both verbal and numerical.

Rating Class Terms

Rating classes are expressed in the tables in terms that indicate the extent to which the soils are limited by all of the soil features that affect a specified use or in terms that indicate the suitability of the soils for the use. Thus, the tables may show limitation classes or suitability classes. Terms for the limitation classes are *not limited, slightly limited, somewhat limited,* and *very limited*. The suitability ratings are expressed as *well suited, moderately well suited, poorly suited,* and *unsuited* or as *good, fair,* and *poor*.

Numerical Ratings

Numerical ratings in the tables indicate the relative severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.00 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact

on the use and the point at which the soil feature is not a limitation. The limitations appear in order from the most limiting to the least limiting. Thus, if more than one limitation is identified, the most severe limitation is listed first and the least severe one is listed last.

Crops and Pasture

General management needed for crops and pasture is suggested in this section. The crops or pasture plants best suited to the soils, including some not commonly grown in the survey area, are identified; the system of land capability classification used by the Natural Resources Conservation Service is explained; and the estimated yields of the main crops, hay, and pasture plants are listed for each soil.

Planners of management systems for individual fields or farms should consider the detailed information given in the description of each soil in the section *Detailed Soil Map Units*. Specific information can be obtained from the local office of the Natural Resources Conservation Service or the Cooperative Extension Service.

Cropland in the survey area comprises about 16,000 acres. The major concerns are a moderate hazard of soil blowing, moderate to low available water capacity, slow water intake rate, and seasonal high water tables.

Soil blowing is best controlled by cropping systems that keep the soil covered during the spring season. Low available water capacity can be overcome by method of irrigation, more frequent light irrigations, and crop selection. Slow water intake rates can be overcome by frequent, light applications after a deep early irrigation. High water tables can be overcome by drainage, crop selection, and irrigation water management.

Fertilization

All crops generally respond favorably to applications of nitrogen fertilizer. On sandy soils or on soils that have regularly received heavy applications of nitrogen and phosphorus, potassium may be needed. On cropland areas, soils should be tested at least every other year to determine present nutrient levels. Due to the high pH (8.0 - 8.5) of most of the soils in the area, some trace elements such as iron and zinc may become limiting. Lowering the pH by applying sulfur allows the trace elements to become available, as well as allowing for more efficient uptake of the major nutrients.

All of the soils in the area have low contents of organic matter. Use of barnyard manure, growing green manure crops that are plowed under, or returning large amounts of crop residues to the soil are beneficial practices. Care should be taken to avoid a buildup of salts when large amounts of manure are used.

Irrigation

All of the cropland in Sandoval County is irrigated. For the most part, water is supplied from the Rio Grande and the Jemez River. *Irrigation water management* is controlling the application of irrigation water in such a way that good crop growth is obtained without wasting water or causing soil erosion.

To irrigate properly, the farmer should know the amount of water the soil will hold, the depth to which plant roots penetrate, and the water requirements of the crop. Most crops should be irrigated when 40 to 50 percent of the available soil moisture has been depleted. A soil probe, auger, or even a shovel can be used to determine the moisture content of the root zone. The most visible symptoms of moisture stress are wilting leaves or leaves that take on a bluish cast. More drought-tolerant plants just exhibit a slow rate of growth. A check of the soil profile should be made about 48 hours after irrigation to determine whether the water reached the desired depth and whether it was applied uniformly. This simple check can reveal many problems of which the producer would not otherwise be aware.

The furrow and border methods are the two primary irrigation methods used in the survey area. The *border* method, which consists of surface flooding between low dikes on leveled land, is most widely used for alfalfa, pastures, and small grain. The *furrow* method, consisting of deeper, large furrows between the rows, is used for row crops.

If water is applied too rapidly on clayey soils such as the Sparham series in the survey area, it runs off or ponds at the lower end of the field. (Alfalfa is easily drowned.) If water is applied too slowly on sandy soils such as the Trail series, it penetrates below the root zone and is lost to plant use. A properly designed irrigation system matches the soil characteristics with the amount of water applied. Concrete-lined ditches and pipelines also are used to help conserve water.

Tillage

Most irrigated soils in this survey area have weak structure or poor tilth. Tillage performed when the soil is wet breaks down the soil structure and compacts the soil, resulting in restricted movement of air and water into the root zone. When farm equipment is driven over wet soil, a compacted layer (usually called a *plowpan*), commonly develops several inches below the surface due to the weight of the equipment. This one- to two-inch thick, tightly compressed layer restricts water intake and is often so dense that plant roots have difficulty penetrating it.

Tillage should be performed at varying depths, and only when the soil is dry, to prevent formation of a plowpan. The effect of such a pan can be corrected by chiseling or subsoiling and by growing deep-rooted crops such as alfalfa. Using a grass crop in a long-term rotation also helps to eliminate such restrictive layers. The practice of minimum tillage limits the number of trips over the field to only those that are essential, and this prevents soil damage. Growing “green manure crops,” which are crops that are plowed under, is also very beneficial to these soils. Both of these practices can improve soil tilth, improve the water intake rate, and improve the soil structure. Minimum tillage also lowers operating costs.

Conservation Cropping

A *conservation cropping sequence* is the growing of crops with the needed cultural and management measures to maintain or improve soil tilth. The conservation cropping sequence should also help to control erosion. Cropping systems include rotations that contain grasses and legumes, as well as rotations that provide benefits without these crops. In this survey area, a simple crop sequence usually is used. The sequence is influenced by the needs and choices of the operator.

Use of Crop Residue

To maintain good crop yields, it is essential to incorporate crop residues into the soil. Stubble from small grains and other crop residues are important sources of organic matter. When residues are incorporated into the soil, soil microorganisms decompose them. This process of decomposition improves the soil structure, which, in turn, improves water intake and increases soil aeration. The organisms also release plant nutrients from the material they are breaking down, and the nutrients again become available to the growing crop.

Alfalfa Production

Alfalfa produces well in the Rio Grande and Jemez Valleys. Alfalfa stands with a density of less than 4 to 5 plants per square foot generally are not profitable and are grassy and weedy. Such stands should be rotated out of alfalfa for 1 to 2 years before replanting to alfalfa. Alfalfa roots produce a chemical that kills alfalfa seedlings and takes at least a year to dissipate. Consequently, at least one other crop should be

grown in the field prior to replanting alfalfa to prevent this early thinning due to the toxin in the soil.

Considerations when planting alfalfa are: 1) avoid soils that have a fluctuating high water table; 2) select the best adapted varieties; 3) prepare a good seedbed; 4) incorporate phosphorus fertilizer before planting; 5) control weeds (fall seedings have fewer weed problems); 6) use correct seeding rate (rates vary depending on variety and seeding method); 7) do not use a companion crop unless needed to prevent soil blowing; and 8) control insects at the proper time.

After a good stand is established, maintain the stand by cutting at about $^{1}/_{10}$ bloom. This is a compromise that provides good quality and quantity without damaging the stand.

Yields per Acre

The average irrigated yields per acre that can be expected of the principal crops under a high level of management are shown in Table 5. In any given year, yields may be higher or lower than those indicated in the table because of variations in rainfall and other climatic factors. The land capability classification of map units in the survey area also is shown in the table.

The yields are based mainly on the experience and records of farmers, conservationists, and extension agents. Available yield data from nearby counties and results of field trials and demonstrations also are considered.

The management needed to obtain the indicated yields of the various crops depends on the kind of soil and the crop. Management can include drainage, erosion control, and protection from flooding; the proper planting and seeding rates; suitable high-yielding crop varieties; appropriate and timely tillage; control of weeds, plant diseases, and harmful insects; favorable soil reaction and optimum levels of nitrogen, phosphorus, potassium, and trace elements for each crop; effective use of crop residue, barnyard manure, and green manure crops; and harvesting that ensures the smallest possible loss.

For yields of irrigated crops, it is assumed that the irrigation system is adapted to the soils and to the crops grown, that good-quality irrigation water is uniformly applied as needed, and that tillage is kept to a minimum.

The estimated yields reflect the productive capacity of each soil for each of the principal crops. Yields are likely to increase as new production technology is developed. The productivity of a given soil compared with that of other soils, however, is not likely to change.

Crops other than those shown in Table 5 are grown in the survey area, but estimated yields are not listed because the acreage of such crops is small. The local office of the Natural Resources Conservation Service or of the Cooperative Extension Service can provide information about the management and productivity of the soils for those crops.

The *productivity index* is a relative rating of the capacity of a soil to produce a specific plant under a defined management system. The index is determined from yield data on a few benchmark soils and is used to calculate yields, the net returns from crops, land assessment values, and taxes and to perform risk analysis when land management decisions are made.

Land Capability Classification

Land capability classification shows, in a general way, the suitability of soils for most kinds of field crops. Crops that require special management are excluded. The soils are grouped according to their limitations for field crops, the risk of damage if they are used for crops, and the way they respond to management. The criteria used in grouping the soils do not include major and generally expensive land forming that would change slope, depth, or other characteristics of the soils, nor do they include

possible but unlikely major reclamation projects. Capability classification is not a substitute for interpretations designed to show suitability and limitations of groups of soils for rangeland, for forestland, or for engineering purposes.

Land capability classifications for the individual soils in this survey can be found in the section *Detailed Soil Map Units*.

In the capability system, soils are generally grouped at two levels—capability class and subclass.

Capability classes, the broadest groups, are designated by the numbers 1 through 8. The numbers indicate progressively greater limitations and narrower choices for practical use. The classes are defined as follows:

Class 1 soils have slight limitations that restrict their use.

Class 2 soils have moderate limitations that restrict the choice of plants or that require moderate conservation practices.

Class 3 soils have severe limitations that restrict the choice of plants or that require special conservation practices, or both.

Class 4 soils have very severe limitations that restrict the choice of plants or that require very careful management, or both.

Class 5 soils are subject to little or no erosion but have other limitations, impractical to remove, that restrict their use mainly to pasture, rangeland, forestland, or wildlife habitat.

Class 6 soils have severe limitations that make them generally unsuitable for cultivation and that restrict their use mainly to pasture, rangeland, forestland, or wildlife habitat.

Class 7 soils have very severe limitations that make them unsuitable for cultivation and that restrict their use mainly to grazing, forestland, or wildlife habitat.

Class 8 soils and miscellaneous areas have limitations that preclude commercial plant production and that restrict their use to recreational purposes, wildlife habitat, watershed, or esthetic purposes.

Capability subclasses are soil groups within one class. They are designated by adding a small letter, *e, w, s,* or *c,* to the class numeral, for example, 2e. The letter *e* shows that the main hazard is the risk of erosion unless close-growing plant cover is maintained; *w* shows that water in or on the soil interferes with plant growth or cultivation (in some soils the wetness can be partly corrected by artificial drainage); *s* shows that the soil is limited mainly because it is shallow, droughty, or stony; and *c,* used in only some parts of the United States, shows that the chief limitation is climate that is very cold or very dry.

In class 1 there are no subclasses because the soils of this class have few limitations. Class 5 contains only the subclasses indicated by *w, s,* or *c* because the soils in class 5 are subject to little or no erosion. They have other limitations that restrict their use to pasture, rangeland, forestland, wildlife habitat, or recreation.

Prime Farmland and Farmland of Statewide and Local Importance

Prime farmland is one of several kinds of important farmland defined by the U.S. Department of Agriculture. It is of major importance in meeting the Nation's short- and long-range needs for food and fiber. Because the supply of high-quality farmland is limited, the U.S. Department of Agriculture recognizes that responsible levels of government, as well as individuals, should encourage and facilitate the wise use of our Nation's prime farmland.

Prime farmland, as defined by the U.S. Department of Agriculture, is land that has the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and is available for these uses. It could be cultivated land, pastureland, forestland, or other land, but it is not urban or built-up land or water areas. The soil qualities, growing season, and moisture supply are those needed for the soil to economically produce sustained high yields of crops

when proper management, including water management, and acceptable farming methods are applied. In general, prime farmland has an adequate and dependable supply of moisture from precipitation or irrigation, a favorable temperature and growing season, acceptable acidity or alkalinity, an acceptable salt and sodium content, and few or no rocks. It is permeable to water and air. It is not excessively erodible or saturated with water for long periods, and it either is not frequently flooded during the growing season or is protected from flooding. Slopes generally range from 0 to 6 percent. More detailed information about the criteria for prime farmland is available at the local office of the Natural Resources Conservation Service There is no farmland in the survey that meets the criteria for prime farmland without supplemental irrigation. Statewide important farmlands are those having an irrigated land capability class of IV or better and are irrigated with a supply of irrigation water that will meet crop needs throughout the growing season.

In some local areas there is a need for certain additional farmlands for the production of food, feed, fiber, and forage, even though these lands are not identified as having national or statewide importance. Where appropriate, these lands are to be identified by the local agency or agencies concerned. In places, additional farmlands of local importance may include tracts of land that have been designated for agriculture by local ordinance.

The map units in the survey area that are considered prime farmland when irrigated listed in Table 6. This list does not constitute a recommendation for a particular land use. On some soils included in the list, measures that overcome a hazard or limitation, such as flooding, wetness, and droughtiness, are needed. Onsite evaluation is needed to determine whether or not the hazard or limitation has been overcome by corrective measures. The location is shown on the detailed soil maps. The soil qualities that affect use and management are described in the section *Detailed Soil Map Units*.

Rangeland

By George Chavez, State Rangeland Management Specialist, Natural Resource Conservation Service

Rangeland is land on which the historic climax plant community is predominantly grasses, grasslike plants, forbs, or shrubs. In areas that have similar climate and topography, the kind and amount of vegetation produced on rangeland is closely related to the kind of soil. Effective management is based on knowledge about the relationship among the soils, vegetation, and water.

The *historic climax plant community* is the association of plants that are best adapted to a unique combination of environmental factors. Even on the same soil, the proportion of these plants varies from place to place and from year to year. The dominant plant or plants are used to characterize the plant community because of their relative stability in areas where abnormal disturbance or deterioration has not occurred. The grasses, forbs and shrubs that characterize the potential natural plant community on each major soil are listed by common name.

Once the plant community has been characterized for each soil, similar plant communities are grouped into ecological sites. An *ecological site* is a distinctive kind of land with specific physical characteristics that differs from other kinds of land in its ability to produce a distinctive kind and amount of vegetation.

Soil properties that have the greatest influence on the productivity of range plants are those that affect the availability of moisture and plant nutrients. Other soil properties such as soil reaction, salt content, and the presence or absence of a high water table during any period of the year, are also important factors in differentiating ecological sites.

Ecological site descriptions can be used to identify the proportions of the total annual production of each plant. Detailed information on the ecological sites in this

survey area is available in the local office of the Natural Resource Conservation Service.

About 55 percent of the survey area is rangeland that supports grasses, forbs, and shrubs suitable for grazing. Yearlong cow and calf operations are the dominant ranch enterprise, but many cattle and sheep ranches and yearling operations are in the area. The livestock produced on these ranches provide the principal agricultural income in the area.

Management of grazing to increase ground cover improves the vigor and reproduction of the more productive grasses and shrubs. Continuous yearlong grazing or grazing the same pasture during the growing season every year may result in the deterioration of the plant community, reducing its value for livestock grazing, watershed, wildlife habitat, and erosion control.

A proper degree of grazing use combined with deferred grazing or prescribed grazing that varies the season of grazing is needed to maintain a healthy, balanced plant community. This practice will also result in high quality forage throughout the year. Periodic rest during different seasons of the year benefits different plants. Rest in summer encourages the production and reproduction of warm-season grasses such as sideoats grama, black grama, galleta, and blue grama. Rest in spring or fall, or both, is beneficial to the cool-season grasses such as western wheatgrass, New Mexico feathergrass, and bottlebrush squirreltail. Rest during fall and winter months benefits shrubs such as fourwing saltbush and winterfat.

Flexibility in livestock and wildlife numbers and in the frequency and intensity of grazing is essential to the success of any grazing program. Effective livestock distribution is accomplished by the proper use of fences, livestock water developments, and salt for livestock.

The major management concern on most rangeland is to control the time and intensity of grazing so that the kinds and amounts of plants that make up the desired plant community may be maintained or reestablished. Forage production often is less than half of the potential because the natural vegetation in many parts of the county has been greatly depleted due to drought, infrequent beneficial wildfires, or continuous and excessive use. Brush, weeds, and cacti have increased or invaded on much of the rangeland, causing further depletion of the grass cover. Soil erosion generally occurs when the soils are not adequately covered.

In many areas where the landscape is broken by mesas, or where pastures are large, the distribution of grazing by livestock generally is poor. Poor distribution of livestock grazing results in areas that are underused and areas that are excessively used. This in turn results in loss of cover, invasion of undesirable plants, and accelerated erosion. Prescribed grazing that improves grazing distribution and proper grazing use is a management concern that may be facilitated by the installation of fencing and additional water. Manipulating or reducing undesirable brush species and minimizing soil erosion are other management concerns.

Table 7 shows, for each soil that supports vegetation suitable for grazing, the ecological site; the total annual production of vegetation in favorable, normal, and unfavorable years; the characteristic vegetation; and the average percentage of each species. An explanation of the column headings in Table 7 follows.

An *ecological site* is the product of all the environmental factors responsible for its development. It has characteristic soils that have developed over time throughout the soil development process; a characteristic hydrology, particularly infiltration and runoff, that has developed over time; and a characteristic plant community (kind and amount of vegetation). The hydrology of the site is influenced by development of the soil and plant community. The vegetation, soils, and hydrology are all interrelated. Each is influenced by the others and influences the development of the others. The plant community on an ecological site is typified by an association of species that differs from that of other ecological sites in the kind and/or proportion of species or in

total production. Descriptions of ecological sites are provided in the Field Office Technical Guide, which is available in local offices of the Natural Resources Conservation Service.

Total dry-weight production is the amount of vegetation that can be expected to grow annually in a well managed area that is supporting the potential natural plant community. It includes all vegetation, whether or not it is palatable to grazing animals. It includes the current year's growth of leaves, twigs, and fruits of woody plants. It does not include the increase in stem diameter of trees and shrubs. It is expressed in pounds per acre of air-dry vegetation for favorable, normal, and unfavorable years. In a favorable year, the amount and distribution of precipitation and the temperatures make growing conditions substantially better than average. In a normal year, growing conditions are about average. In an unfavorable year, growing conditions are well below average, generally because of low available soil moisture. Yields are adjusted to a common percent of air-dry moisture content.

Characteristic vegetation—the grasses, forbs, and shrubs that make up most of the potential natural plant community on each soil—is listed by common name. Under *rangeland composition*, the expected percentage of the total annual production is given for each species making up the characteristic vegetation. The amount that can be used as forage depends on the kinds of grazing animals and on the grazing season.

Range management requires a knowledge of the kinds of soil and of the potential natural plant community. It also requires an evaluation of the present range similarity index and rangeland trend. Range similarity index is determined by comparing the present plant community with the potential natural plant community on a particular rangeland ecological site. The more closely the existing community resembles the potential community, the higher the range similarity index. Rangeland trend is defined as the direction of change in an existing plant community relative to the potential natural plant community. Further information about the range similarity index and rangeland trend is available in the "National Range and Pasture Handbook," which is available in local offices of the Natural Resources Conservation Service.

The objective in range management is to control grazing so that the plants growing on a site are about the same in kind and amount as the potential natural plant community for that site. Such management generally results in the optimum production of vegetation, control of undesirable brush species, conservation of water, and control of erosion. Sometimes, however, an area with a range similarity index somewhat below the potential meets grazing needs, provides wildlife habitat, and protects soil and water resources.

Forest Productivity

The tables in this section can help forest owners or managers plan the use of soils for wood crops. They show the potential productivity of the soils for wood crops and rate the soils according to the limitations that affect various aspects of forest management.

Forest Productivity

In Table 8, the *potential productivity* of merchantable or *common trees* on a soil is expressed as a site index and as a volume number. The *site index* is the average height, in feet, that dominant and codominant trees of a given species attain in a specified number of years. The site index applies to fully stocked, even-aged, unmanaged stands. *Commonly grown trees* are those that forest managers generally favor in intermediate or improvement cuttings. They are selected on the basis of growth rate, quality, value, and marketability. More detailed information regarding site

index is available in the “National Forestry Manual,” which is available in local offices of the Natural Resources Conservation Service or on the Internet.

The *volume of wood fiber*, a number, is the yield likely to be produced by the most important tree species. This number, expressed as cubic feet per acre per year and calculated at the age of culmination of the mean annual increment (CMAI), indicates the amount of fiber produced in a fully stocked, even-aged, unmanaged stand.

Trees to manage are those that are preferred for planting, seeding, or natural regeneration and those that remain in the stand after thinning or partial harvest.

Recreation

The soils of the survey area are rated in Tables 9A and 9B according to limitations that affect their suitability for recreation. The ratings are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect the recreational uses. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Slightly limited* indicates that the soil has features that are favorable for the specified use. The limitations are minor and can be easily overcome. Good performance and low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.00 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

The ratings in the tables are based on restrictive soil features, such as wetness, slope, and texture of the surface layer. Susceptibility to flooding is considered. Not considered in the ratings, but important in evaluating a site, are the location and accessibility of the area, the size and shape of the area and its scenic quality, vegetation, access to water, potential water impoundment sites, and access to public sewer lines. The capacity of the soil to absorb septic tank effluent and the ability of the soil to support vegetation also are important. Soils that are subject to flooding are limited for recreational uses by the duration and intensity of flooding and the season when flooding occurs. In planning recreational facilities, onsite assessment of the height, duration, intensity, and frequency of flooding is essential.

The information in Tables 9A and 9B can be supplemented by other information in this survey, for example, interpretations for building site development, construction materials, sanitary facilities, and water management.

Camp areas require site preparation, such as shaping and leveling the tent and parking areas, stabilizing roads and intensively used areas, and installing sanitary facilities and utility lines. Camp areas are subject to heavy foot traffic and some vehicular traffic. The ratings are based on the soil properties that affect the ease of developing camp areas and the performance of the areas after development. Slope, stoniness, and depth to bedrock or a cemented pan are the main concerns affecting the development of camp areas.

The soil properties that affect the performance of the areas after development are those that influence trafficability and promote the growth of vegetation, especially in heavily used areas. For good trafficability, the surface of camp areas should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The

soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Picnic areas are subject to heavy foot traffic. Most vehicular traffic is confined to access roads and parking areas. The ratings are based on the soil properties that affect the ease of developing picnic areas and that influence trafficability and the growth of vegetation after development. Slope and stoniness are the main concerns affecting the development of picnic areas. For good trafficability, the surface of picnic areas should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Playgrounds require soils that are nearly level, are free of stones, and can withstand intensive foot traffic. The ratings are based on the soil properties that affect the ease of developing playgrounds and that influence trafficability and the growth of vegetation after development. Slope and stoniness are the main concerns affecting the development of playgrounds. For good trafficability, the surface of the playgrounds should absorb rainfall readily, remain firm under heavy foot traffic, and not be dusty when dry. The soil properties that influence trafficability are texture of the surface layer, depth to a water table, ponding, flooding, permeability, and large stones. The soil properties that affect the growth of plants are depth to bedrock or a cemented pan, permeability, and toxic substances in the soil.

Paths and trails for hiking and horseback riding should require little or no slope modification through cutting and filling. The ratings are based on the soil properties that affect trafficability and erodibility. These properties are stoniness, depth to a water table, ponding, flooding, slope, and texture of the surface layer.

Off-road motorcycle trails require little or no site preparation. They are not covered with surfacing material or vegetation. Considerable compaction of the soil material is likely. The ratings are based on the soil properties that influence erodibility, trafficability, dustiness, and the ease of revegetation. These properties are stoniness, slope, depth to a water table, ponding, flooding, and texture of the surface layer.

Golf fairways are subject to heavy foot traffic and some light vehicular traffic. Cutting or filling may be required. Irrigation is not considered in the ratings. The ratings are based on the soil properties that affect plant growth and trafficability after vegetation is established. The properties that affect plant growth are reaction; depth to a water table; ponding; depth to bedrock or a cemented pan; the available water capacity in the upper 40 inches; the content of salts, sodium, or calcium carbonate; and sulfidic materials. The properties that affect trafficability are flooding, depth to a water table, ponding, slope, stoniness, and the amount of sand, clay, or organic matter in the surface layer. The suitability of the soil for traps, tees, roughs, and greens is not considered in the ratings.

Wildlife Habitat

The six general areas containing wildlife habitat in the Sandoval County Area are discussed in the following paragraphs.

Plateaus, mesas, and *terraces* contain soils that have grasslands and pinyon-juniper forests on the gently undulating to steep slopes. Grasses and shrubs grow on soils ranging from very shallow to very deep.

The summits of plateaus and mesas support pinyon-juniper forests. Elevations range from 6,800 to 7,800 feet. A variety of wildlife utilizes these areas, some of which include gray squirrels, cottontail rabbits, prairie rattlesnakes, and pinyon jays.

Fan remnants and stream terraces form near valleys and mountains. These upland sites are home to badger, stripped skunk, prairie dogs, prairie rattlesnakes, black-tailed jackrabbit, and hawks. Antelope could be reintroduced in the northern half of the survey if given protection until established. Badgers and other burrowing animals make extensive use of areas of coarse and moderately coarse textured soils.

Mountains occur in the northeastern portion of the survey area north of Bernalillo. The Jemez Mountains contain some of the most important wildlife habitat in the survey area. Woodlands of ponderosa pine, Douglas-fir, pinyon, juniper, and Gambel oak, provide habitat for turkey, mule deer, Elk, black bear, porcupine, cottontail rabbits, gray squirrel, band-tailed pigeons, owls, hawks, prairie rattlesnakes, and songbirds.

Open grassy valleys are home to prairie dogs. The Long tailed weasel also occurs in these areas. Local wetlands are important for many birds, waterfowl, and local mammals. Steep slopes and variable topography also play important roles in wildlife habitat.

River and stream valleys occur along such streams as the Rio Grande, Rio Puerco, and Jemez River. They contain riparian vegetation and water for wildlife use. These areas are used by all local wildlife for some part of their needs.

Songbirds nest in cottonwood and willow trees in large numbers. Cavity nesting birds find many nest sites in holes within large cottonwood trees. Quail use the thick vegetation for cover and seed sources. The abundant prey species attract many predators such as coyote, hawks, prairie rattlesnakes, and bobcat. Mule deer may spend their whole lives in these river bottoms.

The potential for competition between livestock and wildlife is high. The plant communities in these riparian areas must be maintained in good condition to provide wildlife habitat, flood protection, water quality, and soil erosion control.

Wetlands are areas containing hydrophytic vegetation, hydric soils, and wetland hydrology. Marshes are wetlands dominated by grasses and grass-like plants, and they occur in few areas of the survey area. Some are in channels of the Rio Grande, Rio Puerco, and Jemez River valleys and are produced by ground water. Other small marshes are man-induced and formed by irrigation impoundments.

All of these wetlands are used extensively by a large variety of wildlife species. Predators and prey species alike gather at these oases in an otherwise dry landscape.

Wetlands provide natural protection from flooding, enhance water quality, furnish habitat for wildlife, and conserve water. Wetlands need protection from excessive grazing, drainage projects, and poorly planned urban development.

Breaks are the steep, broken lands on the escarpments of mesas and plateaus. Breaks are very eroded and dissected, with many small ridges and gullies. Vegetation grows on the soils occurring in breaks, but not in large amounts. Although annual production of air-dry vegetation is generally low, plant diversity is high. This botanic diversity along with the physical cover provided by the terrain provides an attractive habitat for wildlife. Mule deer hide in breaks and feed on browse plants such as true mountainmahogany. Coyote and red fox find cover in the intricate, rocky landscapes. Trees growing on breaks of higher elevation provide nest sites and hunting perches for raptors such as the red-tailed hawk.

Rock outcrops furnish wildlife habitat when they occur as cliffs below rims of plateaus, mesas, and canyons. Although little or no vegetation grows on rock outcrops, they are still important to many species. Eagles, hawks, turkey vultures, owls, diamondback rattlers, and swallows utilize cliffs and ledges. Migratory bats seasonally roost in cracks and caves. Foxes, bobcats, bear, and cougars have dens in alcoves and caves.

Engineering

This section provides information for planning land uses related to urban development and to water management. Soils are rated for various uses, and the most limiting features are identified. Ratings are given for building site development, sanitary facilities, construction materials, and water management. The ratings are based on observed performance of the soils and on the estimated data and test data in the *Soil Properties* section.

Information in this section is intended for land use planning, for evaluating land use alternatives, and for planning site investigations prior to design and construction. The information, however, has limitations. For example, estimates and other data generally apply only to that part of the soil between the surface and a depth of 5 to 7 feet. Because of the map scale, small areas of different soils may be included within the mapped areas of a specific soil.

The information is not site specific and does not eliminate the need for onsite investigation of the soils or for testing and analysis by personnel experienced in the design and construction of engineering works.

Government ordinances and regulations that restrict certain land uses or impose specific design criteria were not considered in preparing the information in this section. Local ordinances and regulations should be considered in planning, in site selection, and in design.

Soil properties, site features, and observed performance were considered in determining the ratings in this section. During the fieldwork for this soil survey, determinations were made about particle-size distribution, liquid limit, plasticity index, soil reaction, depth to bedrock, hardness of bedrock within 5 to 7 feet of the surface, soil wetness, depth to a water table, ponding, slope, likelihood of flooding, natural soil structure aggregation, and soil density. Data were collected about kinds of clay minerals, mineralogy of the sand and silt fractions, and the kinds of adsorbed cations. Estimates were made for erodibility, permeability, corrosivity, shrink-swell potential, available water capacity, and other behavioral characteristics affecting engineering uses.

This information can be used to evaluate the potential of areas for residential, commercial, industrial, and recreational uses; make preliminary estimates of construction conditions; evaluate alternative routes for roads, streets, highways, pipelines, and underground cables; evaluate alternative sites for sanitary landfills, septic tank absorption fields, and sewage lagoons; plan detailed onsite investigations of soils and geology; locate potential sources of gravel, sand, earthfill, and topsoil; plan drainage systems, irrigation systems, ponds, terraces, and other structures for soil and water conservation; and predict performance of proposed small structures and pavements by comparing the performance of existing similar structures on the same or similar soils.

The information in the tables, along with the soil maps, the soil descriptions, and other data provided in this survey, can be used to make additional interpretations.

Some of the terms used in this soil survey have a special meaning in soil science and are defined in the *Glossary*.

Building Site Development

Soil properties influence the development of building sites, including the selection of the site, the design of the structure, construction, performance after construction, and maintenance. Tables 10A and 10B show the degree and kind of soil limitations that affect dwellings with and without basements, small commercial buildings, local roads and streets, shallow excavations, and lawns and landscaping.

The ratings in the tables are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect building

site development. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Slightly limited* indicates that the soil has features that are favorable for the specified use. The limitations are minor and can be easily overcome. Good performance and low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.00 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

Dwellings are single-family houses of three stories or less. For dwellings without basements, the foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of 2 feet or at the depth of maximum frost penetration, whichever is deeper. For dwellings with basements, the foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of about 7 feet. The ratings for dwellings are based on the soil properties that affect the capacity of the soil to support a load without movement and on the properties that affect excavation and construction costs. The properties that affect the load-supporting capacity include depth to a water table, ponding, flooding, subsidence, linear extensibility (shrink-swell potential), and compressibility. Compressibility is inferred from the Unified classification. The properties that affect the ease and amount of excavation include depth to a water table, ponding, flooding, slope, depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, and the amount and size of rock fragments.

Small commercial buildings are structures that are less than three stories high and do not have basements. The foundation is assumed to consist of spread footings of reinforced concrete built on undisturbed soil at a depth of 2 feet or at the depth of maximum frost penetration, whichever is deeper. The ratings are based on the soil properties that affect the capacity of the soil to support a load without movement and on the properties that affect excavation and construction costs. The properties that affect the load-supporting capacity include depth to a water table, ponding, flooding, subsidence, linear extensibility (shrink-swell potential), and compressibility (which is inferred from the Unified classification). The properties that affect the ease and amount of excavation include flooding, depth to a water table, ponding, slope, depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, and the amount and size of rock fragments.

Local roads and streets have an all-weather surface and carry automobile and light truck traffic all year. They have a subgrade of cut or fill soil material; a base of gravel, crushed rock, or soil material stabilized by lime or cement; and a surface of flexible material (asphalt), rigid material (concrete), or gravel with a binder. The ratings are based on the soil properties that affect the ease of excavation and grading and the traffic-supporting capacity. The properties that affect the ease of excavation and grading are depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, depth to a water table, ponding, flooding, the amount of large stones, and slope. The properties that affect the traffic-supporting capacity are soil strength (as inferred from the AASHTO group index number), subsidence, linear extensibility (shrink-swell potential), the potential for frost action, depth to a water table, and ponding.

Shallow excavations are trenches or holes dug to a maximum depth of 5 or 6 feet for graves, utility lines, open ditches, or other purposes. The ratings are based on the soil properties that influence the ease of digging and the resistance to sloughing. Depth to bedrock or a cemented pan, hardness of bedrock or a cemented pan, the amount of large stones, and dense layers influence the ease of digging, filling, and compacting. Depth to the seasonal high water table, flooding, and ponding may restrict the period when excavations can be made. Slope influences the ease of using machinery. Soil texture, depth to the water table, and linear extensibility (shrink-swell potential) influence the resistance to sloughing.

Lawns and landscaping require soils on which turf and ornamental trees and shrubs can be established and maintained. Irrigation is not considered in the ratings. The ratings are based on the soil properties that affect plant growth and trafficability after vegetation is established. The properties that affect plant growth are reaction; depth to a water table; ponding; depth to bedrock or a cemented pan; the available water capacity in the upper 40 inches; the content of salts, sodium, or calcium carbonate; and sulfidic materials. The properties that affect trafficability are flooding, depth to a water table, ponding, slope, stoniness, and the amount of sand, clay, or organic matter in the surface layer.

Sanitary Facilities

Tables 11A and 11B show the degree and kind of soil limitations that affect septic tank absorption fields, sewage lagoons, sanitary landfills, and daily cover for landfill. The ratings are both verbal and numerical. Rating class terms indicate the extent to which the soils are limited by all of the soil features that affect these uses. *Not limited* indicates that the soil has features that are very favorable for the specified use. Good performance and very low maintenance can be expected. *Slightly limited* indicates that the soil has features that are favorable for the specified use. The limitations are minor and can be easily overcome. Good performance and low maintenance can be expected. *Somewhat limited* indicates that the soil has features that are moderately favorable for the specified use. The limitations can be overcome or minimized by special planning, design, or installation. Fair performance and moderate maintenance can be expected. *Very limited* indicates that the soil has one or more features that are unfavorable for the specified use. The limitations generally cannot be overcome without major soil reclamation, special design, or expensive installation procedures. Poor performance and high maintenance can be expected.

Numerical ratings in the tables indicate the severity of individual limitations. The ratings are shown as decimal fractions ranging from 0.00 to 1.00. They indicate gradations between the point at which a soil feature has the greatest negative impact on the use (1.00) and the point at which the soil feature is not a limitation (0.00).

Septic tank absorption fields are areas in which effluent from a septic tank is distributed into the soil through subsurface tiles or perforated pipe. Only that part of the soil between depths of 24 and 60 inches is evaluated. The ratings are based on the soil properties that affect absorption of the effluent, construction and maintenance of the system, and public health. Permeability, depth to a water table, ponding, depth to bedrock or a cemented pan, and flooding affect absorption of the effluent. Stones and boulders, ice, and bedrock or a cemented pan interfere with installation. Subsidence interferes with installation and maintenance. Excessive slope may cause lateral seepage and surfacing of the effluent in downslope areas.

Some soils are underlain by loose sand and gravel or fractured bedrock at a depth of less than 4 feet below the distribution lines. In these soils the absorption field may not adequately filter the effluent, particularly when the system is new. As a result, the ground water may become contaminated.

Sewage lagoons are shallow ponds constructed to hold sewage while aerobic bacteria decompose the solid and liquid wastes. Lagoons should have a nearly level

floor surrounded by cut slopes or embankments of compacted soil. Nearly impervious soil material for the lagoon floor and sides is required to minimize seepage and contamination of ground water. Considered in the ratings are slope, permeability, depth to a water table, ponding, depth to bedrock or a cemented pan, flooding, large stones, and content of organic matter.

Soil permeability is a critical property affecting the suitability for sewage lagoons. Most porous soils eventually become sealed when they are used as sites for sewage lagoons. Until sealing occurs, however, the hazard of pollution is severe. Soils that have a permeability rate of more than 2 inches per hour are too porous for the proper functioning of sewage lagoons. In these soils, seepage of the effluent can result in contamination of the ground water. Ground-water contamination is also a hazard if fractured bedrock is within a depth of 40 inches, if the water table is high enough to raise the level of sewage in the lagoon, or if floodwater overtops the lagoon.

A high content of organic matter is detrimental to proper functioning of the lagoon because it inhibits aerobic activity. Slope, bedrock, and cemented pans can cause construction problems, and large stones can hinder compaction of the lagoon floor. If the lagoon is to be uniformly deep throughout, the slope must be gentle enough and the soil material must be thick enough over bedrock or a cemented pan to make land smoothing practical.

A *trench sanitary landfill* is an area where solid waste is placed in successive layers in an excavated trench. The waste is spread, compacted, and covered daily with a thin layer of soil excavated at the site. When the trench is full, a final cover of soil material at least 2 feet thick is placed over the landfill. The ratings in the table are based on the soil properties that affect the risk of pollution, the ease of excavation, trafficability, and revegetation. These properties include permeability, depth to bedrock or a cemented pan, depth to a water table, ponding, slope, flooding, texture, stones and boulders, highly organic layers, soil reaction, and content of salts and sodium. Unless otherwise stated, the ratings apply only to that part of the soil within a depth of about 6 feet. For deeper trenches, onsite investigation may be needed.

Hard, nonrippable bedrock, creviced bedrock, or highly permeable strata in or directly below the proposed trench bottom can affect the ease of excavation and the hazard of ground-water pollution. Slope affects construction of the trenches and the movement of surface water around the landfill. It also affects the construction and performance of roads in areas of the landfill.

Soil texture and consistence affect the ease with which the trench is dug and the ease with which the soil can be used as daily or final cover. They determine the workability of the soil when dry and when wet. Soils that are plastic and sticky when wet are difficult to excavate, grade, or compact and are difficult to place as a uniformly thick cover over a layer of refuse.

The soil material used as the final cover for a trench landfill should be suitable for plants. It should not have excess sodium or salts and should not be too acid. The surface layer generally has the best workability, the highest content of organic matter, and the best potential for plants. Material from the surface layer should be stockpiled for use as the final cover.

In an *area sanitary landfill*, solid waste is placed in successive layers on the surface of the soil. The waste is spread, compacted, and covered daily with a thin layer of soil from a source away from the site. A final cover of soil material at least 2 feet thick is placed over the completed landfill. The ratings in the table are based on the soil properties that affect trafficability and the risk of pollution. These properties include flooding, permeability, depth to a water table, ponding, slope, and depth to bedrock or a cemented pan.

Flooding is a serious problem because it can result in pollution in areas downstream from the landfill. If permeability is too rapid or if fractured bedrock, a fractured cemented pan, or the water table is close to the surface, the leachate can

contaminate the water supply. Slope is a consideration because of the extra grading required to maintain roads in the steeper areas of the landfill. Also, leachate may flow along the surface of the soils in the steeper areas and cause difficult seepage problems.

Daily cover for landfill is the soil material that is used to cover compacted solid waste in an area sanitary landfill. The soil material is obtained offsite, transported to the landfill, and spread over the waste. The ratings in the table also apply to the final cover for a landfill. They are based on the soil properties that affect workability, the ease of digging, and the ease of moving and spreading the material over the refuse daily during wet and dry periods. These properties include soil texture, depth to a water table, ponding, rock fragments, slope, depth to bedrock or a cemented pan, reaction, and content of salts, sodium, or lime.

Loamy or silty soils that are free of large stones and excess gravel are the best cover for a landfill. Clayey soils may be sticky and difficult to spread; sandy soils are subject to wind erosion.

Slope affects the ease of excavation and of moving the cover material. Also, it can influence runoff, erosion, and reclamation of the borrow area.

After soil material has been removed, the soil material remaining in the borrow area must be thick enough over bedrock, a cemented pan, or the water table to permit revegetation. The soil material used as the final cover for a landfill should be suitable for plants. It should not have excess sodium, salts, or lime and should not be too acid.

Construction Materials

Tables 12A and 12B give information about the soils as potential sources of gravel, sand, topsoil, reclamation material, and roadfill. Normal compaction, minor processing, and other standard construction practices are assumed.

The soils are rated *good, fair,* or *poor* as potential sources of topsoil, reclamation material, and roadfill. The features that limit the soils as sources of these materials are specified in the tables. The numerical ratings given after the specified features indicate the degree to which the features limit the soils as sources of topsoil, reclamation material, or roadfill. The lower the number, the greater the limitation.

The soils are rated as a *probable* or *improbable* source of sand and gravel. A rating of *probable* means that the source material is likely to be in or below the soil. The numerical ratings in these columns indicate the degree of probability. The number 0.00 indicates that the soil is an improbable source. A number between 0.00 and 1.00 indicates the degree to which the soil is a probable source of sand or gravel.

Sand and *gravel* are natural aggregates suitable for commercial use with a minimum of processing. They are used in many kinds of construction. Specifications for each use vary widely. In Table 12A, only the probability of finding material in suitable quantity is evaluated. The suitability of the material for specific purposes is not evaluated, nor are factors that affect excavation of the material. The properties used to evaluate the soil as a source of sand or gravel are gradation of grain sizes (as indicated by the Unified classification of the soil), the thickness of suitable material, and the content of rock fragments. If the lowest layer of the soil contains sand or gravel, the soil is rated as a probable source regardless of thickness. The assumption is that the sand or gravel layer below the depth of observation exceeds the minimum thickness.

Topsoil is used to cover an area so that vegetation can be established and maintained. The upper 40 inches of a soil is evaluated for use as topsoil. Also evaluated is the reclamation potential of the borrow area. The ratings are based on the soil properties that affect plant growth; the ease of excavating, loading, and spreading the material; and reclamation of the borrow area. Toxic substances, soil reaction, and the properties that are inferred from soil texture, such as available water

capacity and fertility, affect plant growth. The ease of excavating, loading, and spreading is affected by rock fragments, slope, depth to a water table, soil texture, and thickness of suitable material. Reclamation of the borrow area is affected by slope, depth to a water table, rock fragments, depth to bedrock or a cemented pan, and toxic material.

The surface layer of most soils is generally preferred for topsoil because of its organic matter content. Organic matter greatly increases the absorption and retention of moisture and nutrients for plant growth.

Reclamation material is used in areas that have been drastically disturbed by surface mining or similar activities. When these areas are reclaimed, layers of soil material or unconsolidated geological material, or both, are replaced in a vertical sequence. The reconstructed soil favors plant growth. The ratings in the table do not apply to quarries and other mined areas that require an offsite source of reconstruction material. The ratings are based on the soil properties that affect erosion and stability of the surface and the productive potential of the reconstructed soil. These properties include the content of sodium, salts, and calcium carbonate; reaction; available water capacity; erodibility; texture; content of rock fragments; and content of organic matter and other features that affect fertility.

Roadfill is soil material that is excavated in one place and used in road embankments in another place. In the table, the soils are rated as a source of roadfill for low embankments, generally less than 6 feet high and less exacting in design than higher embankments.

The ratings are for the whole soil, from the surface to a depth of about 5 feet. It is assumed that soil layers will be mixed when the soil material is excavated and spread.

The ratings are based on the amount of suitable material and on soil properties that affect the ease of excavation and the performance of the material after it is in place. The thickness of the suitable material is a major consideration. The ease of excavation is affected by large stones, depth to a water table, and slope. How well the soil performs in place after it has been compacted and drained is determined by its strength (as inferred from the AASHTO classification of the soil) and linear extensibility (shrink-swell potential).

Water Management

Table 13 gives information on the soil properties and site features that affect water management. The degree and kind of soil limitations are given for pond reservoir areas; embankments, dikes, and levees; and aquifer-fed excavated ponds. The limitations are considered *slight* if soil properties and site features are generally favorable for the indicated use and limitations are minor and are easily overcome; *moderate* if soil properties or site features are not favorable for the indicated use and special planning, design, or maintenance is needed to overcome or minimize the limitations; and *severe* if soil properties or site features are so unfavorable or so difficult to overcome that special design, significant increase in construction costs, and possibly increased maintenance are required.

Table 13 also gives, for each soil, the restrictive features that affect drainage, irrigation, terraces and diversions, and grassed waterways.

Pond reservoir areas hold water behind a dam or embankment. Soils best suited to this use have low seepage potential in the upper 60 inches. The seepage potential is determined by the permeability of the soil and the depth to fractured bedrock or other permeable material. Excessive slope can affect the storage capacity of the reservoir area.

Embankments, dikes, and levees are raised structures of soil material, generally less than 20 feet high, constructed to impound water or to protect land against overflow. In this table, the soils are rated as a source of material for embankment fill.

The ratings apply to the soil material below the surface layer to a depth of about 5 feet. It is assumed that soil layers will be uniformly mixed and compacted during construction.

The ratings do not indicate the ability of the natural soil to support an embankment. Soil properties to a depth even greater than the height of the embankment can affect performance and safety of the embankment. Generally, deeper onsite investigation is needed to determine these properties.

Soil material in embankments must be resistant to seepage, piping, and erosion and have favorable compaction characteristics. Unfavorable features include less than 5 feet of suitable material and a high content of stones or boulders, organic matter, or salts or sodium. A high water table affects the amount of usable material. It also affects trafficability.

Aquifer-fed excavated ponds are pits or dugouts that extend to a ground-water aquifer or to a depth below a permanent water table. Excluded are ponds that are fed only by surface runoff and embankment ponds that impound water 3 feet or more above the original surface. Excavated ponds are affected by depth to a permanent water table, permeability of the aquifer, and quality of the water as inferred from the salinity of the soil. Depth to bedrock and the content of large stones affect the ease of excavation.

Drainage is the removal of excess surface and subsurface water from the soil. How easily and effectively the soil is drained depends on the depth to bedrock, a cemented pan, or other layers that affect the rate of water movement; permeability; depth to a high water table or depth of standing water if the soil is subject to ponding; slope; susceptibility to flooding; subsidence of organic layers; and the potential for frost action. Excavating and grading and the stability of ditchbanks are affected by depth to bedrock or a cemented pan, large stones, slope, and the hazard of cutbanks caving. The productivity of the soil after drainage is adversely affected by extreme acidity or by toxic substances in the root zone, such as salts, sodium, and sulfur. Availability of drainage outlets is not considered in the ratings.

Irrigation is the controlled application of water to supplement rainfall and support plant growth. The design and management of an irrigation system are affected by depth to the water table, the need for drainage, flooding, available water capacity, intake rate, permeability, erosion hazard, and slope. The construction of a system is affected by large stones and depth to bedrock or a cemented pan. The performance of a system is affected by the depth of the root zone, the amount of salts or sodium, and soil reaction.

Terraces and diversions are embankments or a combination of channels and ridges constructed across a slope to control erosion and conserve moisture by intercepting runoff. Slope, wetness, large stones, and depth to bedrock or a cemented pan affect the construction of terraces and diversions. A restricted rooting depth, a severe hazard of wind erosion or water erosion, an excessively coarse texture, and restricted permeability adversely affect maintenance.

Grassed waterways are natural or constructed channels, generally broad and shallow, that conduct surface water to outlets at a nonerosive velocity. Large stones, wetness, slope, and depth to bedrock or a cemented pan affect the construction of grassed waterways. A hazard of wind erosion, low available water capacity, restricted rooting depth, toxic substances such as salts and sodium, and restricted permeability adversely affect the growth and maintenance of the grass after construction.

Soil Properties

Data relating to soil properties are collected during the course of the soil survey.

Soil properties are ascertained by field examination of the soils and by laboratory index testing of some benchmark soils. Established standard procedures are followed. During the survey, many shallow borings are made and examined to identify and classify the soils and to delineate them on the soil maps. Samples are taken from some typical profiles and tested in the laboratory to determine particle-size distribution, plasticity, and compaction characteristics.

Estimates of soil properties are based on field examinations, on laboratory tests of samples from the survey area, and on laboratory tests of samples of similar soils in nearby areas. Tests verify field observations, verify properties that cannot be estimated accurately by field observation, and help to characterize key soils.

The estimates of soil properties are shown in tables. They include engineering index properties, physical and chemical properties, and pertinent soil and water features.

Engineering Index Properties

Table 14 gives the engineering classifications and the range of index properties for the layers of each soil in the survey area.

Depth to the upper and lower boundaries of each layer is indicated.

Texture is given in the standard terms used by the U.S. Department of Agriculture. These terms are defined according to percentages of sand, silt, and clay in the fraction of the soil that is less than 2 millimeters in diameter. “Loam,” for example, is soil that is 7 to 27 percent clay, 28 to 50 percent silt, and less than 52 percent sand. If the content of particles coarser than sand is 15 percent or more, an appropriate modifier is added, for example, “gravelly.” Textural terms are defined in the *Glossary*.

Classification of the soils is determined according to the Unified soil classification system (ASTM, 1998) and the system adopted by the American Association of State Highway and Transportation Officials (AASHTO, 1998).

The Unified system classifies soils according to properties that affect their use as construction material. Soils are classified according to particle-size distribution of the fraction less than 3 inches in diameter and according to plasticity index, liquid limit, and organic matter content. Sandy and gravelly soils are identified as GW, GP, GM, GC, SW, SP, SM, and SC; silty and clayey soils as ML, CL, OL, MH, CH, and OH; and highly organic soils as PT. Soils exhibiting engineering properties of two groups can have a dual classification, for example, CL-ML.

The AASHTO system classifies soils according to those properties that affect roadway construction and maintenance. In this system, the fraction of a mineral soil that is less than 3 inches in diameter is classified in one of seven groups from A-1 through A-7 on the basis of particle-size distribution, liquid limit, and plasticity index. Soils in group A-1 are coarse grained and low in content of fines (silt and clay). At the other extreme, soils in group A-7 are fine grained. Highly organic soils are classified in group A-8 on the basis of visual inspection.

Rock fragments larger than 10 inches in diameter and 3 to 10 inches in diameter are indicated as a percentage of the total soil on a dry-weight basis. The percentages

are estimates determined mainly by converting volume percentage in the field to weight percentage.

Percentage (of soil particles) passing designated sieves is the percentage of the soil fraction less than 3 inches in diameter based on an ovendry weight. The sieves, numbers 4, 10, 40, and 200 (USA Standard Series), have openings of 4.76, 2.00, 0.420, and 0.074 millimeters, respectively. Estimates are based on laboratory tests of soils sampled in the survey area and in nearby areas and on estimates made in the field.

Liquid limit and *plasticity index* (Atterberg limits) indicate the plasticity characteristics of a soil. The estimates are based on test data from the survey area or from nearby areas and on field examination.

The estimates of particle-size distribution, liquid limit, and plasticity index are generally rounded to the nearest 5 percent. Thus, if the ranges of gradation and Atterberg limits extend a marginal amount (1 or 2 percentage points) across classification boundaries, the classification in the marginal zone is generally omitted in the table.

Physical Properties

Table 15 shows estimates of some physical characteristics and features that affect soil behavior. These estimates are given for the layers of each soil in the survey area. The estimates are based on field observations and on test data for these and similar soils.

Depth to the upper and lower boundaries of each layer is indicated.

Particle size is the effective diameter of a soil particle as measured by sedimentation, sieving, or micrometric methods. Particle sizes are expressed as classes with specific effective diameter class limits. The broad classes are sand, silt, and clay, ranging from the larger to the smaller.

Sand as a soil separate consists of mineral soil particles that are 0.05 millimeter to 2 millimeters in diameter. In Table 15, the estimated sand content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

Silt as a soil separate consists of mineral soil particles that are 0.002 to 0.05 millimeter in diameter. In Table 15, the estimated silt content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

Clay as a soil separate consists of mineral soil particles that are less than 0.002 millimeter in diameter. In Table 15, the estimated clay content of each soil layer is given as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

The content of sand, silt, and clay affects the physical behavior of a soil. Particle size is important for engineering and agronomic interpretations, for determination of soil hydrologic qualities, and for soil classification.

The amount and kind of clay affect the fertility and physical condition of the soil and the ability of the soil to adsorb cations and to retain moisture. They influence shrink-swell potential, permeability, plasticity, the ease of soil dispersion, and other soil properties. The amount and kind of clay in a soil also affect tillage and earthmoving operations.

Moist bulk density is the weight of soil (ovendry) per unit volume. Volume is measured when the soil is at field moisture capacity, that is, the moisture content at $^1/_3$- or $^1/_{10}$-bar (33kPa or 10kPa) moisture tension. Weight is determined after the soil is dried at 105 degrees C. In the table, the estimated moist bulk density of each soil horizon is expressed in grams per cubic centimeter of soil material that is less than 2 millimeters in diameter. Bulk density data are used to compute shrink-swell potential,

available water capacity, total pore space, and other soil properties. The moist bulk density of a soil indicates the pore space available for water and roots. Depending on soil texture, a bulk density of more than 1.4 can restrict water storage and root penetration. Moist bulk density is influenced by texture, kind of clay, content of organic matter, and soil structure.

Permeability (K_{sat}) refers to the ability of a soil to transmit water or air. The term "permeability," as used in soil surveys, indicates saturated hydraulic conductivity (K_{sat}). The estimates in the table indicate the rate of water movement, in inches per hour, when the soil is saturated. They are based on soil characteristics observed in the field, particularly structure, porosity, and texture. Permeability is considered in the design of soil drainage systems and septic tank absorption fields.

Available water capacity refers to the quantity of water that the soil is capable of storing for use by plants. The capacity for water storage is given in inches of water per inch of soil for each soil layer. The capacity varies, depending on soil properties that affect retention of water. The most important properties are the content of organic matter, soil texture, bulk density, and soil structure. Available water capacity is an important factor in the choice of plants or crops to be grown and in the design and management of irrigation systems. Available water capacity is not an estimate of the quantity of water actually available to plants at any given time.

Linear extensibility refers to the change in length of an unconfined clod as moisture content is decreased from a moist to a dry state. It is an expression of the volume change between the water content of the clod at $^1/_3$- or $^1/_{10}$-bar tension (33kPa or 10kPa tension) and oven dryness. The volume change is reported in the table as percent change for the whole soil. Volume change is influenced by the amount and type of clay minerals in the soil.

Linear extensibility is used to determine the shrink-swell potential of soils. The shrink-swell potential is low if the soil has a linear extensibility of less than 3 percent; moderate if 3 to 6 percent; high if 6 to 9 percent; and very high if more than 9 percent. If the linear extensibility is more than 3, shrinking and swelling can cause damage to buildings, roads, and other structures and to plant roots. Special design commonly is needed.

Organic matter is the plant and animal residue in the soil at various stages of decomposition. In Table 15, the estimated content of organic matter is expressed as a percentage, by weight, of the soil material that is less than 2 millimeters in diameter.

The content of organic matter in a soil can be maintained by returning crop residue to the soil. Organic matter has a positive effect on available water capacity, water infiltration, soil organism activity, and tilth. It is a source of nitrogen and other nutrients for crops and soil organisms.

Erosion factors are shown in Table 15 as the K factor (Kw and Kf) and the T factor. Erosion factor K indicates the susceptibility of a soil to sheet and rill erosion by water. Factor K is one of several factors used in the Universal Soil Loss Equation (USLE) and the Revised Universal Soil Loss Equation (RUSLE) to predict the average annual rate of soil loss by sheet and rill erosion in tons per acre per year. The estimates are based primarily on percentage of silt, sand, and organic matter and on soil structure and permeability. Values of K range from 0.02 to 0.69. Other factors being equal, the higher the value, the more susceptible the soil is to sheet and rill erosion by water.

Erosion factor Kw indicates the erodibility of the whole soil. The estimates are modified by the presence of rock fragments.

Erosion factor Kf indicates the erodibility of the fine-earth fraction, or the material less than 2 millimeters in size.

Erosion factor T is an estimate of the maximum average annual rate of soil erosion by wind or water that can occur without affecting crop productivity over a sustained period. The rate is in tons per acre per year.

Wind erodibility groups are made up of soils that have similar properties affecting their susceptibility to wind erosion in cultivated areas. The soils assigned to group 1 are the most susceptible to wind erosion, and those assigned to group 8 are the least susceptible. The groups are as follows:

1. Coarse sands, sands, fine sands, and very fine sands.
2. Loamy coarse sands, loamy sands, loamy fine sands, loamy very fine sands, ash material, and sapric soil material.
3. Coarse sandy loams, sandy loams, fine sandy loams, and very fine sandy loams.

4L. Calcareous loams, silt loams, clay loams, and silty clay loams.

4. Clays, silty clays, noncalcareous clay loams, and silty clay loams that are more than 35 percent clay.
5. Noncalcareous loams and silt loams that are less than 20 percent clay and sandy clay loams, sandy clays, and hemic soil material.
6. Noncalcareous loams and silt loams that are more than 20 percent clay and noncalcareous clay loams that are less than 35 percent clay.
7. Silts, noncalcareous silty clay loams that are less than 35 percent clay, and fibric soil material.
8. Soils that are not subject to wind erosion because of coarse fragments on the surface or because of surface wetness.

Wind erodibility index is a numerical value indicating the susceptibility of soil to wind erosion, or the tons per acre per year that can be expected to be lost to wind erosion. There is a close correlation between wind erosion and the texture of the surface layer, the size and durability of surface clods, rock fragments, organic matter, and a calcareous reaction. Soil moisture and frozen soil layers also influence wind erosion.

Chemical Properties

Table 16 shows estimates of some chemical characteristics and features that affect soil behavior. These estimates are given for the layers of each soil in the survey area. The estimates are based on field observations and on test data for these and similar soils.

Depth to the upper and lower boundaries of each layer is indicated.

Cation-exchange capacity is the total amount of extractable bases that can be held by the soil, expressed in terms of milliequivalents per 100 grams of soil at neutrality (pH 7.0) or at some other stated pH value. Soils having a low cation-exchange capacity hold fewer cations and may require more frequent applications of fertilizer than soils having a high cation-exchange capacity. The ability to retain cations reduces the hazard of ground-water pollution.

Soil reaction is a measure of acidity or alkalinity. The pH of each soil horizon is based on many field tests. For many soils, values have been verified by laboratory analyses. Soil reaction is important in selecting crops and other plants, in evaluating soil amendments for fertility and stabilization, and in determining the risk of corrosion.

Calcium carbonate equivalent is the percent of carbonates, by weight, in the fraction of the soil less than 2 millimeters in size. The availability of plant nutrients is influenced by the amount of carbonates in the soil. Incorporating nitrogen fertilizer into calcareous soils helps to prevent nitrite accumulation and ammonium-N volatilization.

Gypsum is expressed as a percent, by weight, of hydrated calcium sulfates in the fraction of the soil less than 20 millimeters in size. Gypsum is partially soluble in water. Soils that have a high content of gypsum may collapse if the gypsum is removed by percolating water.

Salinity is a measure of soluble salts in the soil at saturation. It is expressed as the electrical conductivity of the saturation extract, in millimhos per centimeter at 25 degrees C. Estimates are based on field and laboratory measurements at representative sites of nonirrigated soils. The salinity of irrigated soils is affected by the quality of the irrigation water and by the frequency of water application. Hence, the salinity of soils in individual fields can differ greatly from the value given in the table. Salinity affects the suitability of a soil for crop production, the stability of soil if used as construction material, and the potential of the soil to corrode metal and concrete.

Sodium adsorption ratio (SAR) is a measure of the amount of sodium (Na) relative to calcium (Ca) and magnesium (Mg) in the water extract from saturated soil paste. It is the ratio of the Na concentration divided by the square root of one-half of the Ca + Mg concentration. Soils that have SAR values of 13 or more may be characterized by an increased dispersion of organic matter and clay particles, reduced permeability and aeration, and a general degradation of soil structure.

Soil Features

Table 17 gives estimates of various soil features. The estimates are used in land use planning that involves engineering considerations.

A *restrictive layer* is a nearly continuous layer that has one or more physical, chemical, or thermal properties that significantly impede the movement of water and air through the soil or that restrict roots or otherwise provide an unfavorable root environment. Examples are bedrock, cemented layers, dense layers, and frozen layers.

Potential for frost action is the likelihood of upward or lateral expansion of the soil caused by the formation of segregated ice lenses (frost heave) and the subsequent collapse of the soil and loss of strength on thawing. Frost action occurs when moisture moves into the freezing zone of the soil. Temperature, texture, density, permeability, content of organic matter, and depth to the water table are the most important factors considered in evaluating the potential for frost action. It is assumed that the soil is not insulated by vegetation or snow and is not artificially drained. Silty and highly structured, clayey soils that have a high water table in winter are the most susceptible to frost action. Well drained, very gravelly, or very sandy soils are the least susceptible. Frost heave and low soil strength during thawing cause damage to pavements and other rigid structures.

Risk of corrosion pertains to potential soil-induced electrochemical or chemical action that corrodes or weakens uncoated steel or concrete. The rate of corrosion of uncoated steel is related to such factors as soil moisture, particle-size distribution, acidity, and electrical conductivity of the soil. The rate of corrosion of concrete is based mainly on the sulfate and sodium content, texture, moisture content, and acidity of the soil. Special site examination and design may be needed if the combination of factors results in a severe hazard of corrosion. The steel or concrete in installations that intersect soil boundaries or soil layers is more susceptible to corrosion than the steel or concrete in installations that are entirely within one kind of soil or within one soil layer.

For uncoated steel, the risk of corrosion, expressed as *low, moderate,* or *high,* is based on soil drainage class, total acidity, electrical resistivity near field capacity, and electrical conductivity of the saturation extract.

For concrete, the risk of corrosion also is expressed as *low, moderate,* or *high*. It is based on soil texture, acidity, and amount of sulfates in the saturation extract.

Water Features

Table 18 gives estimates of various water features. The estimates are used in land use planning that involves engineering considerations.

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The four hydrologic soil groups are:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas.

The *months* in the table indicate the portion of the year in which the feature is most likely to be a concern.

Water table refers to a saturated zone in the soil. Table 18 indicates, by month, depth to the top (*upper limit*) and base (*lower limit*) of the saturated zone in most years. Estimates of the upper and lower limits are based mainly on observations of the water table at selected sites and on evidence of a saturated zone, namely grayish colors or mottles (redoximorphic features) in the soil. A saturated zone that lasts for less than a month is not considered a water table.

Ponding is standing water in a closed depression. Unless a drainage system is installed, the water is removed only by percolation, transpiration, or evaporation. Table 18 indicates *surface water depth* and the *duration* and *frequency* of ponding. Duration is expressed as *very brief* if less than 2 days, *brief* if 2 to 7 days, *long* if 7 to 30 days, and *very long* if more than 30 days. Frequency is expressed as none, rare, occasional, and frequent. *None* means that ponding is not probable; *rare* that it is unlikely but possible under unusual weather conditions (the chance of ponding is nearly 0 percent to 5 percent in any year); *occasional* that it occurs, on the average, once or less in 2 years (the chance of ponding is 5 to 50 percent in any year); and *frequent* that it occurs, on the average, more than once in 2 years (the chance of ponding is more than 50 percent in any year).

Flooding is the temporary inundation of an area caused by overflowing streams, by runoff from adjacent slopes, or by tides. Water standing for short periods after rainfall or snowmelt is not considered flooding, and water standing in swamps and marshes is considered ponding rather than flooding.

Duration and *frequency* are estimated. Duration is expressed as *extremely brief* if 0.1 hour to 4 hours, *very brief* if 4 hours to 2 days, *brief* if 2 to 7 days, *long* if 7 to 30 days, and *very long* if more than 30 days. Frequency is expressed as none, very rare,

rare, occasional, frequent, and very frequent. *None* means that flooding is not probable; *very rare* that it is very unlikely but possible under extremely unusual weather conditions (the chance of flooding is less than 1 percent in any year); *rare* that it is unlikely but possible under unusual weather conditions (the chance of flooding is 1 to 5 percent in any year); *occasional* that it occurs infrequently under normal weather conditions (the chance of flooding is 5 to 50 percent in any year); *frequent* that it is likely to occur often under normal weather conditions (the chance of flooding is more than 50 percent in any year but is less than 50 percent in all months in any year); and *very frequent* that it is likely to occur very often under normal weather conditions (the chance of flooding is more than 50 percent in all months of any year).

The information is based on evidence in the soil profile, namely thin strata of gravel, sand, silt, or clay deposited by floodwater; irregular decrease in organic matter content with increasing depth; and little or no horizon development.

Also considered are local information about the extent and levels of flooding and the relation of each soil on the landscape to historic floods. Information on the extent of flooding based on soil data is less specific than that provided by detailed engineering surveys that delineate flood-prone areas at specific flood frequency levels.

Classification of the Soils

Soils are classified so that we can more easily remember significant characteristics. Classification enables us to assemble knowledge about the soils, to see their relationship to one another and to the whole environment, and to develop principles that help us to understand their behavior and their responses to manipulation. Through classification and then the use of soil maps, we can apply our knowledge of soils to specific areas.

The system of soil classification used by the National Cooperative Soil Survey has six categories (USDA, 1998 and 1999). Beginning with the broadest, these categories are the order, suborder, great group, subgroup, family, and series. Classification is based on soil properties observed in the field or inferred from those observations or from laboratory measurements. Table 19 shows the classification of the soils in the survey area. The categories are defined in the following paragraphs.

ORDER. Twelve soil orders are recognized. The differences among orders reflect the dominant soil-forming processes and the degree of soil formation. Each order is identified by a word ending in *sol*. An example is Aridisol.

SUBORDER. Each order is divided into suborders primarily on the basis of properties that influence soil genesis and are important to plant growth or properties that reflect the most important variables within the orders. The last syllable in the name of a suborder indicates the order. An example is Argid (*Arg*, meaning presence of argillic horizon, plus *id*, from Aridisol).

GREAT GROUP. Each suborder is divided into great groups on the basis of close similarities in kind, arrangement, and degree of development of pedogenic horizons; soil moisture and temperature regimes; type of saturation; and base status. Each great group is identified by the name of a suborder and by a prefix that indicates a property of the soil. An example is Haplargids (*Hapl*, meaning minimal horizonation, plus *argid*, the suborder of the Aridisols that has a argillic horizon).

SUBGROUP. Each great group has a typic subgroup. Other subgroups are intergrades or extragrades. The typic subgroup is the central concept of the great group; it is not necessarily the most extensive. Intergrades are transitions to other orders, suborders, or great groups. Extragrades have some properties that are not representative of the great group but do not indicate transitions to any other taxonomic class. Each subgroup is identified by one or more adjectives preceding the name of the great group. The adjective *Typic* identifies the subgroup that typifies the great group. An example is Typic Haplargids.

FAMILY. Families are established within a subgroup on the basis of physical and chemical properties and other characteristics that affect management. Generally, the properties are those of horizons below plow depth where there is much biological activity. Among the properties and characteristics considered are particle size, mineral content, soil temperature regime, soil depth, and reaction. A family name consists of the name of a subgroup preceded by terms that indicate soil properties. An example is fine-loamy, mixed, , mesic Typic Haplargids.

SERIES. The series consists of soils within a family that have horizons similar in color, texture, structure, reaction, consistence, mineral and chemical composition, and arrangement in the profile. The Grieta series is an example of a fine-loamy, mixed, mesic Typic Haplargid.

Soil Series and Their Morphology

In this section, each soil series recognized in the survey area is described. Characteristics of the soil and the material in which it formed are identified for each series. A pedon, a small three-dimensional area of soil, that is typical of the series in the survey area is described. The detailed description of each soil horizon follows standards in the “Soil Survey Manual” (USDA, 1993). Many of the technical terms used in the descriptions are defined in “Soil Taxonomy” (USDA, 1975,). Unless otherwise indicated, colors in the descriptions are for moist soil. Following the pedon description is the range of important characteristics of the soils in the series.

The classifications given in Table 19 are those of the classifications at the time of correlation of this survey (1987).

Aga Series

Map units: 22, 27, 426, 427, 428, 827
Depth class: very deep
Drainage class: moderately well drained
Landform: flood plains
Parent material: stream alluvium derived from mixed sources
Elevation: 5,000 to 6,000 feet (1,524 to 1,829 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Coarse-loamy over sandy or sandy-skeletal, mixed, calcareous, mesic Typic Torrifluvents

Typical Pedon

Aga loam, in an area of mapping unit 27, Aga loam, 0 to 1 percent slopes; Sandoval County; Santo Domingo Pueblo Quadrangle, unsectionized state plane coordinates N. 1,659,900 feet and E. 471,850 feet. NAD 83, UTM 13—03 78 346 E—39 35 898 N.

A—0 to 10 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; many fine and very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.

C1—10 to 23 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; common fine and very fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.

2C2—23 to 43 inches; light yellowish brown (10YR 6/4) sand, yellowish brown (10YR 5/4) moist; single grain; loose, nonsticky and nonplastic; few fine and very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.

2C3—43 to 60 inches; very pale brown (10YR 7/4) sand, light yellowish brown (10YR 6/4) moist; single grain; loose, nonsticky and nonplastic; 10 percent gravel; slightly effervescent; moderately alkaline.

Range in Characteristics

A horizon
Texture: loam or silty clay loam

C horizon
Texture: very fine sandy loam

2C horizon
Hue: 10YR or 7.5YR
Value: 5 to 7 when dry, and 4 to 6 when moist
Chroma: 3 or 4
Texture: sand, loamy sand, gravelly sand, or loamy fine sand
Salinity: from less than 2 to 16 mmhos/cm.

Note: The water table ranges from 4 to 6 feet.

Alanos Series

Map units: 283, 290
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes and hillsides
Parent material: slope alluvium and colluvium derived from tuff and rhyolite
Elevation: 7,800 to 9,500 feet (2,377 to 2,896 meters)
Slope: 5 to 40 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Clayey-skeletal, mixed Typic Eutroboralfs

Typical Pedon

Alanos loam, in an area of mapping unit 290, Alanos-Rock outcrop complex, 20 to 40 percent slopes; Los Alamos County; Frijoles Quadrangle. NAD 83, UTM 13—03 78 360 E—39 67 869 N.

A—0 to 4 inches; grayish brown (10YR 5/2) loam, dark grayish brown (10YR 4/2) moist; weak fine granular structure; soft, very friable, slightly sticky and nonplastic; many fine and medium roots; 10 percent gravel; neutral; abrupt smooth boundary.
E—4 to 9 inches; light gray (10YR 7/2) loam, grayish brown (10YR 5/2) moist; weak fine granular structure; slightly hard, very friable, nonsticky and nonplastic; common fine roots; few fine vesicular pores; 10 percent gravel; neutral; abrupt smooth boundary.
BE—9 to 18 inches; pinkish gray (7.5YR 7/2) and reddish brown (5YR 5/4) very gravelly loam, brown (7.5YR 5/2) and reddish brown (5YR 4/4) moist; weak fine subangular blocky structure; hard, very friable, slightly sticky and slightly plastic; common very fine roots; common fine black (5YR 2/1) iron and manganese concretions; 55 percent gravel; medium acid; clear smooth boundary.
Bt1—18 to 26 inches; reddish brown (5YR 5/4) extremely gravelly clay, reddish brown (5YR 4/4) moist; weak fine subangular blocky structure; hard, firm, sticky and plastic; few fine roots; few fine tubular pores; common fine black (5YR 2/1) iron and manganese concretions; common thin clay films in pores and on gravel; 20 percent cobbles and 55 percent gravel; medium acid; clear smooth boundary.
Bt2—26 to 60 inches; brown (7.5YR 5/4) extremely gravelly clay, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; few fine roots; few fine tubular pores; few thin clay films in pores and on gravel; 20 percent cobbles and 55 percent gravel; medium acid.

Range in Characteristics

Particle-size control section: 35 to 55 percent clay
Other features: Some pedons are slightly alkaline in the lower subhorizons.

A horizon
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 3 to 5 moist
Chroma: 2 or 3
Texture: loam or cobbly loam

E horizon
Hue: 7.5YR or 10YR
Value: 6 or 7 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: loam, gravelly loam, or cobbly loam

Bt horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 3 to 6 moist
Chroma: 2 to 6
Texture: extremely gravelly clay loam, extremely gravelly clay, or very gravelly clay
Concretions: fine or medium iron and manganese concretions are in the upper part of the Bt horizon.

Note: C horizons are below 38 inches in some pedons.

Atarque Series

Map units: 324, 396
Depth class: very shallow to shallow
Drainage class: well drained
Landform: breaks; dipslopes of cuestas, hills, mesas, and ridges
Parent material: slope alluvium derived from sandstone and shale
Elevation: 5,700 to 6,600 feet (1,737 to 2,012 meters)
Slope: 5 to 45 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy, mixed, mesic Lithic Haplustalfs

Typical Pedon

Atarque sandy loam, in an area of mapping unit 324, Rock outcrop-Atarque-Menefee complex, 5 to 25 percent slopes; Sandoval County; Ponderosa Quadrangle; about 2 miles northeast of the Jemez Pueblo; 200 feet south and 1,400 feet east of the northwest corner of sec. 11, T 16 N, R 2 E. NAD 27; UTM 13—03 45 805 E—39 44 974 N.

A—0 to 3 inches; light brown (7.5YR 6/4) sandy loam, dark brown (7.5YR 4/4) moist; moderate very thin platy structure; soft, very friable, nonsticky and nonplastic; many very fine roots; neutral; clear smooth boundary.
Bt—3 to 9 inches; reddish brown (5YR 5/4) sandy clay loam, reddish brown (5YR 4/4) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; common very fine roots; many very fine tubular pores; many thin clay films on faces of peds and lining pores; neutral; clear smooth boundary.

Btk—9 to 14 inches; strong brown (7.5YR 5/6) sandy clay loam, strong brown (7.5YR 4/6) moist; weak moderate subangular blocky structure; hard, firm, sticky and plastic; few very fine roots; many very fine tubular pores; common thin clay films on faces of peds and lining pores; violently effervescent; common fine irregular shaped soft masses of calcium carbonate; slightly alkaline.
R—14 inches; sandstone bedrock.

Range in Characteristics

A horizon
Hue: 10YR to 5YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 6
Texture: sandy loam or extremely gravelly sandy loam

B horizons
Hue: 10YR to 5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: sandy clay loam or clay loam

Note: Depth to bedrock: 6 to 20 inches

Bamac Series

Map units: 300, 319, 345, 346
Depth class: very deep
Drainage class: excessively drained
Landform: alluvial fans, fan remnants, fan terraces, hills, and ridges
Parent material: slope and fan alluvium derived from mixed sources
Elevation: 5,400 to 6,900 feet (1,646 to 2,103 meters)
Slope: 1 to 55 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Sandy-skeletal, mixed, mesic Typic Ustorthents

Typical Pedon

Bamac very gravelly loamy sand, in an area of mapping unit 319, Bamac-Rock outcrop complex, 15 to 55 percent slopes; Sandoval County; Santo Domingo Pueblo SW Quadrangle; about 2.5 miles southwest of the Cochiti Pueblo; 2,550 feet east and 100 feet south of the northwest corner of sec. 26, T. 16 N., R. 5 E. NAD 83, UTM 13—03 74 829 E—39 39 774 N.

A—0 to 4 inches; light yellowish brown (10YR 6/4) very gravelly loamy sand, dark yellowish brown (10YR 4/4) moist; weak very fine granular structure; soft, very friable, nonsticky and nonplastic; common fine and medium roots; 55 percent gravel; slightly effervescent; moderately alkaline; clear smooth boundary.
AC—4 to 10 inches; light yellowish brown (10YR 6/4) loamy sand, brown (10YR 4/3) moist; weak medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; common medium roots; 10 percent gravel; slightly effervescent; moderately alkaline; clear wavy boundary.
C1—10 to 21 inches; very pale brown (10YR 7/3) very gravelly loamy coarse sand, brown (10YR 5/3) moist; massive; soft, very friable, nonsticky and nonplastic; few

fine roots; 45 percent gravel; slightly effervescent; moderately alkaline; gradual wavy boundary

C2—21 to 37 inches; pale brown (10YR 6/3) very gravelly loamy coarse sand, brown (10YR 4/3) moist; massive; soft, very friable, nonsticky and nonplastic; 55 percent gravel; slightly effervescent; moderately alkaline; gradual wavy boundary.

C3—37 to 60 inches; pink (7.5YR 7/4) very gravelly loamy coarse sand, yellowish brown (10YR 5/4) moist; massive; soft, very friable, nonsticky and nonplastic; 50 percent gravel; slightly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 0 to 5 percent clay

A horizon

Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: Gravelly or very gravelly loamy sand or sandy loam or extremely gravelly coarse sandy loam

C horizon

Hue: 7.5YR or 10YR
Value: 3 to 7 dry, 4 to 6 moist
Chroma: 3 to 6 moist or dry
Texture: very gravelly coarse sand, very gravelly loamy sand, or very gravelly loamy coarse sand. Some pedons have thin strata of loamy sand or coarse sand.

Note: Some pedons have Ck horizons.

Betonnie Series

Map unit: 150
Depth class: very deep
Drainage class: well drained
Landform: dipslopes on cuestas, fan terraces, hills, valley sides, summits of plateaus and mesas
Parent material: eolian material and slope alluvium derived from sandstone
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 5 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Coarse-loamy, mixed, mesic Ustalfic Haplargids

Typical Pedon

Betonnie fine sandy loam, in an area of mapping unit 150, Doakum-Betonnie fine sandy loams, 0 to 8 percent slopes; Sandoval County; Mule Dam Quadrangle; about 15 miles south of Councelor and 500 feet south and 2,400 feet west of the northeast corner of sec. 29, T. 22 N., R. 6 W. NAD 83, UTM 13—02 75 951 E—39 99 372 N.

A—0 to 2 inches; light yellowish brown (10YR 6/4) fine sandy loam, yellowish brown (10YR 5/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few very fine roots; few very fine and fine continuous pores; moderately alkaline; clear smooth boundary.

BA—2 to 4 inches; brown (7.5YR 5/4) fine sandy loam, brown (7.5YR 4/4) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; common very fine and fine roots; common very fine and fine continuous pores; moderately alkaline; clear smooth boundary.

Bt—4 to 12 inches; brown (7.5YR 5/4) fine sandy loam, dark brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and medium roots; common fine continuous pores; clay bridging sand grains and few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

BC—12 to 18 inches; brown (7.5YR 5/4) sandy loam, brown (7.5YR 4/4) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and nonplastic; few very fine roots; few very fine continuous pores; moderately alkaline; clear smooth boundary.

C1—18 to 34 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, slightly sticky and nonplastic; few very fine roots; strongly effervescent; strongly alkaline; clear gradual boundary.

C2—34 to 60 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; slightly hard, firm, slightly sticky and nonplastic; strongly effervescent; moderately alkaline.

Range in Characteristics

A horizon

Hue: 7.5YR or 10YR
Value: 5 to 6 dry, 3 or 5 moist
Chroma: 3 or 4
Texture: loamy fine sand, fine sandy loam, or sandy loam

Bt horizon

Hue: 5YR or 7.5YR
Value: 4 to 6 dry and moist
Chroma: 3 to 6
Texture: fine sandy loam or sandy loam

C horizon

Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 4 to 6 moist
Chroma: 3 to 6
Texture: fine sandy loam, loamy sand, and sandy loam

Note: Some pedons have Bk horizons; some contain thin strata of loamy sand.

Blancot Series

Map units: 101, 270
Depth class: very deep
Drainage class: well drained
Landform: valley sides and ridges
Parent material: fan alluvium derived from sandstone and shale
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 2 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, mesic Ustalfic Haplargids

Typical Pedon

Blancot fine sandy loam, in an area of mapping unit 101, Blancot-Lybrook association, 0 to 8 percent slopes; Sandoval County; Galisteo Quadrangle; about 2,580 feet north and 1,450 feet east of the southwest corner of sec. 15, T. 22 N., R. 7 W. NAD 83, UTM 13—02 69 104 E—40 02 257 N.

A—0 to 2 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few very fine and fine roots; few very fine and fine continuous pores; moderately alkaline; clear smooth boundary.

Bt1—2 to 5 inches; grayish brown (10YR 5/2) clay loam, brown (10YR 4/3) moist; moderate fine subangular blocky structure; slightly hard, friable, sticky and plastic; common fine and medium roots; common very fine and fine continuous pores; few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

Bt2—5 to 14 inches; yellowish brown (10YR 5/4) clay loam, dark yellowish brown (10YR 4/4) moist; moderate fine subangular blocky structure; slightly hard, firm, slightly sticky and slightly plastic; common very fine and fine continuous pores; few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

Btk—14 to 23 inches; yellowish brown (10YR 5/4) clay loam, yellowish brown (10YR 5/4) moist; weak fine subangular blocky structure; hard, firm, slightly sticky and slightly plastic; few very fine and fine roots; few very fine and fine continuous pores; few thin clay films on faces of peds; strongly effervescent; moderately alkaline; clear smooth boundary.

C1—23 to 40 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; hard, friable, nonsticky and nonplastic; few very fine and fine roots; slightly effervescent; moderately alkaline; clear gradual boundary.

C2—40 to 49 inches; light brownish gray (10YR 6/2) silty clay loam, grayish brown (10YR 5/2) moist; massive; slightly hard, friable, sticky and plastic; strongly effervescent; moderately alkaline; clear gradual boundary.

C2—49 to 60 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; slightly hard, friable, nonsticky and nonplastic; strongly effervescent; strongly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
- *Hue:* 10YR or 2.5Y
- *Value:* 5 to 7 dry, 3 to 5 moist
- *Chroma:* 2 to 4
- *Texture:* fine sandy loam, loam, or silt loam

Bt horizon
- *Hue:* 10YR or 2.5Y
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 2 to 6 dry and moist
- *Texture:* loam, sandy clay loam, or clay loam

Btk, Bk, and C horizons (when present)
- *Hue:* 10YR or 2.5Y
- *Value:* 5 or 6 dry, 3 to 5 moist
- *Chroma:* 2 to 6 dry and moist
- *Texture:* sandy loam, loam, sandy clay loam, clay loam, fine sandy loam, or silty clay loam

Note: Some pedons have accumulations of secondary calcium carbonate.

Bond Series

Map unit: 227
Depth class: very shallow to shallow
Drainage class: well drained
Landform: cuestas, hills, mesas, and ridges
Parent material: eolian material and slope alluvium derived from sandstone
Elevation: 5,700 to 6,000 feet (1,737 to 1,829 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy, mixed, mesic Lithic Ustollic Haplargids

Typical Pedon

Bond loamy fine sand, in an area of mapping unit 227, Hagerman-Bond association, 1 to 8 percent slopes; Sandoval County; Ojito Spring Quadrangle; about 3/4 mile north and 1/2 mile east of the Ojito Spring (along the Ojito Arroyo) on the Zia Pueblo portion of the Ojo Del Espiritu Santo Grant. NAD 83, UTM 13—03 23 191 E—39 39 809 N.

A—0 to 4 inches; light yellowish brown (10YR 6/4) loamy fine sand, yellowish brown (10YR 5/4) moist; weak fine granular structure; slightly hard, very friable, nonsticky and nonplastic; many fine and few medium roots; slightly alkaline; clear smooth boundary.
Bt—4 to 12 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine roots; few fine tubular pores; common thin clay films on faces of peds; neutral; abrupt smooth boundary.
R—12 inches; sandstone bedrock.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Depth to lithic contact: 6 to 20 inches

A horizon
Hue: 5YR, 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: loamy fine sand, sandy loam, or fine sandy loam

Bt horizon
Hue: 5YR or 7.5YR
Value: 4 or 6 dry, 3 to 6 moist
Chroma: 3 to 6
Texture: sandy clay loam, loam, sandy loam, or clay loam

C horizon (when present)
Hue: 5YR or 7.5YR
Value: 5 to 8 dry, 5 or 6 moist
Chroma: 4 to 6 dry and moist
Texture: sandy clay loam, loam, sandy loam, or clay loam

Note: Some pedons have Btk horizons.

Cajete Series

Map units: 308, 503
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes, hills, and stream terraces
Parent material: residuum derived from pumice
Elevation: 7,000 to 8,500 feet (2,134 to 2,591 meters)
Slope: 0 to 30 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Ashy-skeletal, frigid Mollic Vitrandepts

Typical Pedon

Cajete gravelly loam, in an area of mapping unit 308, Cajete gravelly loam, 0 to 8 percent slopes; Sandoval County; Redondo Peak Quadrangle; about 100 yards south of dirt tank and 10 yards north of ridge crest, Baca location No. 1. NAD 83, UTM 13—03 58 759 E—39 66 454 N.

A1—0 to 7 inches; very dark grayish brown (10YR 3/2) gravelly loam, very dark brown (10YR 2/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and medium roots; 20 percent pumice gravel; neutral; clear smooth boundary.

A2—7 to 15 inches; dark grayish brown (10YR 4/2) gravelly loam, very dark grayish brown (10YR 3/2) moist; weak medium subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; many fine and medium roots; 20 percent pumice gravel; neutral; gradual wavy boundary.

Bw—15 to 33 inches; pale brown (10YR 6/3) very gravelly sandy loam, yellowish brown (10YR 5/4) moist; weak fine and medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; many fine and medium roots; 40 percent pumice gravel; neutral; abrupt wavy boundary.

C1—33 to 45 inches; matrix: light gray (10YR 7/2) very gravelly sand, pale brown (10YR 6/3) moist; single grain; loose, nonsticky and nonplastic; many fine and medium roots concentrated near lamella; wavy lamella 0.5 to 1 inch thick, strong brown (7.5YR 5/6) extremely gravelly sandy loam, yellowish brown (10YR 5/6) moist, 75 percent pumice gravel; matrix has 50 percent pumice gravel; neutral; abrupt wavy boundary.

C2—45 to 49 inches; very pale brown (10YR 7/3) extremely gravelly sand, light yellowish brown (10YR 6/4) moist; single grain; loose, nonsticky and nonplastic; 60 percent pumice gravel; slightly alkaline; abrupt wavy boundary.

C3—49 to 60 inches; matrix; light gray (10YR 7/2) very gravelly sand, pale brown (10YR 6/3) and light yellowish brown (10YR 6/4) moist; single grain; loose, nonsticky and nonplastic; lamella 0.25-0.5 inch thick with colors similar to those described in the C1; 50 percent fine pumice gravel; slightly alkaline.

Range in Characteristics

Depth to the base of the cambic horizon: 20 to 35 inches

A horizons
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 1 to 3
Texture: extremely gravelly coarse sandy loam or gravelly loam
Content of rock fragments: 15 to 80 percent pumice

Bw horizon
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 5 or 6 moist
Chroma: 2 to 4
Content of rock fragments: 35 to 60 percent pumice gravel

C horizons
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 5 to 6 moist
Chroma: 2 to 4
Texture: very gravelly sand or very gravelly sandy loam
Content of rock fragments: 35 to 60 percent pumice

Calaveras Series

Map units: 82, 83, 311
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: colluvium derived from tuff
Elevation: 8,500 to 9,200 feet (2,591 to 2,804 meters)
Slope: 5 to 60 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed, frigid Dystric Eutrochrepts

Typical Pedon

Calaveras silt loam, in an area of mapping unit 311, Cosey-Tranquilar-Calaveras association, 5 to 20 percent slopes; Sandoval County, Valle San Antonio Quadrangle; about .1 mile south of movie set on the main ranch road, Baca Location No. 1; NAD 83, UTM 13—03 63 714 E—39 71 088 N.

A—0 to 4 inches; grayish brown (10YR 5/2) silt loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; many very fine and fine roots; 5 percent gravel; slightly acid; clear smooth boundary.

E—4 to 11 inches; pale brown (10YR 6/3) silt loam, dark yellowish brown (10YR 3/4) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and medium roots; 10 percent gravel; slightly acid; clear smooth boundary.

Bw—11 to 17 inches; pale brown (10YR 6/3) gravelly silt loam, dark brown (10YR 4/3) moist; weak coarse subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common coarse roots; 5 percent stones and 20 percent gravel; slightly acid; clear wavy boundary.

2Bt1—17 to 30 inches; pale brown (10YR 6/3) very cobbly loam, dark brown (10YR 4/3) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common coarse roots; few thin patchy clay films on rock fragments; 5 percent stones, 20 percent cobbles, and 20 percent gravel; medium acid; gradual wavy boundary.

2Bt2—30 to 39 inches; light brown (7.5YR 6/4) extremely cobbly coarse sandy loam, brown (7.5YR 5/4) moist; weak fine and medium subangular blocky structure; hard, firm, slightly sticky and slightly plastic; few coarse roots; many clay films bridging sand grains and many thick clay films occur on tops of rock fragments; 5 percent stones, 30 percent cobbles, and 30 percent gravel; neutral; gradual wavy boundary.

3Bt3—39 to 60 inches; light brown (7.5YR 6/4) extremely cobbly loamy sand, brown (7.5YR 5/4) moist; weak fine subangular blocky structure; hard, firm, slightly sticky and slightly plastic; few coarse roots; clay bridging sand grains; 10 percent stones, 30 percent cobbles, and 20 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 5 to 20 percent clay
Content of rock fragments: 10 to 85 percent total; 0 to 50 percent stones or cobbles, and 15 to 50 percent gravel

A horizon
Hue: 10YR or 7.5YR
Value: 3 to 7 dry, 2 to 5 moist
Chroma: 1 to 4
Texture: silt loam, loam, or very gravelly sandy loam

E horizon
Hue: 7.5YR or 10YR
Value: 6 or 7 dry, 3 or 4 moist
Chroma: 2 to 4
Texture: silt loam and sandy clay loam

2B horizons
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: extremely cobbly coarse sandy loam, very cobbly sandy loam, or very cobbly loam. In some pedons, extremely cobbly loamy coarse sand or extremely cobbly loamy sand occurs below 35 inches.

Note: Some pedons may have an AE horizon of sandy loam texture.

Camino Series

Map unit: 15
Depth class: deep
Drainage class: well drained
Landform: valley sides and plateaus
Parent material: fan alluvium and residuum derived from shale
Elevation: 5,900 to 6,200 feet (1,798 to 1,890 meters)
Slope: 1 to 6 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine, mixed, mesic Ustollic Camborthids

Typical Pedon

Camino silty clay loam, in an area of mapping unit 15, Camino-Sandoval complex, 1 to 8 percent slopes; Sandoval County; Sky Village NW Quadrangle; on Alamo Ranch 800 feet south and 400 feet east of the northwest corner of sec. 14, T. 14 N., R. 1 W. NAD 83, UTM 13—03 25 862 E—39 24 200 N.

A—0 to 2 inches; pale olive (5Y 6/3) silty clay loam, olive (5Y 5/3) moist; weak fine subangular blocky structure; soft, friable, sticky and plastic; few very fine roots; strongly effervescent; slightly alkaline; abrupt smooth boundary.

Bw1—2 to 5 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; weak medium subangular blocky structure; very hard, very firm, very sticky and very plastic; few fine and very fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.

Bw2—5 to 20 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; weak medium subangular blocky structure; very hard, very firm, very sticky and very plastic; few fine and very fine roots; strongly effervescent; few fine irregular soft masses of calcium carbonate; moderately alkaline; gradual smooth boundary.

Bk—20 to 51 inches; pale olive (5Y 6/3) clay, olive (5Y 5/3) moist; massive; very hard, very firm, very sticky and very plastic; 5 percent shale fragments; strongly effervescent; common fine irregular soft masses of calcium carbonate; moderately alkaline; clear wavy boundary.

Cr—51 inches; soft olive shale.

Range in Characteristics

Particle-size control section: 40 to 50 percent clay
Salinity: EC of 2 to 4
Depth to bedrock: 40 to more than 60 inches

A horizon
- *Hue:* 2.5Y or 5Y
- *Value:* 5 or 6 dry, 4 or 5 moist
- *Chroma:* 3 or 4

Bw and Bk horizons
- *Hue:* 2.5Y or 5Y
- *Value:* 5 to 7 dry, 4 to 6 moist
- *Chroma:* 3 or 4

Carjo Series

Map unit: 281
Depth class: moderately deep
Drainage class: well drained
Landform: hills, mesas, and summits of ridges
Parent material: residuum derived from tuff
Elevation: 7,000 to 8,000 feet (2,134 to 2,438 meters)
Slope: 1 to 9 percent
Climatic data:
- *Mean annual precipitation:* 20 to 25 inches (508 to 635 millimeters)
- *Mean annual air temperature:* 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
- *Frost-free period:* 60 to 90 days

Taxonomic class: Fine, mixed Mollic Eutroboralfs

Typical Pedon

Carjo loam, in an area of mapping unit 281, Carjo loam, 1 to 9 percent slopes; Los Alamos County; Frijoles Quadrangle; at the east end of 2-mile mesa; 1,100 feet south and 1,500 feet west of the northeast corner of sec. 20, T. 19 N., R. 6 E. NAD 83, UTM 13—03 80 426 E—39 70 016 N.

A—0 to 4 inches; grayish brown (10YR 5/2) loam, very dark grayish brown (10YR 3/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine roots; many very fine interstitial pores; neutral; clear smooth boundary.

BA—4 to 12 inches; brown (7.5YR 4/4) clay loam, dark brown (7.5YR 3/4) moist; weak fine subangular blocky structure; slightly hard, very friable, sticky and plastic; many fine roots; many very fine interstitial pores; neutral; clear smooth boundary.

Bt—12 to 20 inches; reddish brown (5YR 4/4) clay, dark reddish brown (5YR 3/4) moist; moderate fine angular blocky structure; hard, firm, sticky and plastic; many fine and medium roots; common fine tubular pores; thin discontinuous clay films on faces of peds; neutral; clear smooth boundary.

C—20 to 25 inches; light brown (7.5YR 6/4) very fine sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few fine roots; common fine tubular pores; slightly alkaline; abrupt smooth boundary.

2R—25 inches; tuff bedrock.

Range in Characteristics

Depth to bedrock: 20 to 40 inches

A horizon
- *Hue:* 7.5YR or 10YR
- *Value:* 3 to 5 dry, 2 or 3 moist
- *Chroma:* 1 to 5
- *Texture:* fine sandy loam or loam
- *Content of rock fragments:* 0 to 35 percent cobbles or flagstones, 0 to 15 percent gravel or channers

B horizon
- *Hue:* 10YR, 7.5YR or 5YR
- *Value:* 3 to 6 dry, 2 to 5 moist
- *Chroma:* 2 to 6
- *Texture:* clay or clay loam
- *Content of rock fragments:* 0 to 15 percent

C or BC horizon
- *Hue:* 7.5YR or 5YR
- *Value:* 5 or 6 dry, 4 or 5 moist
- *Chroma:* 3 or 4
- *Texture:* sandy loam, very fine sandy loam, or clay loam

Note: B/E or E horizons occur in some pedons.

Cascajo Series

Map units: 47, 54
Depth class: very deep
Drainage class: excessively drained
Landform: hills, knolls, ridges, and structural benches
Parent material: fan alluvium derived from sandstone
Elevation: 5,300 to 6,500 feet (1,615 to 1,981 meters)

Slope: 5 to 30 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Sandy-skeletal, mixed, mesic Ustollic Calciorthids

Typical Pedon

Cascajo very gravelly sandy loam, in an area of mapping unit 47, Cascajo very gravelly sandy loam, 12 to 30 percent slopes; Sandoval County; San Felipe Pueblo Quadrangle; about 7 miles northeast of Ball Ranch Headquarters; 600 feet west and 700 feet south of the northeast corner of sec. 27, T. 14 N., R. 6 E. NAD 27; UTM 13—03 83 258 E—39 20 070 N.

A—0 to 2 inches; pale brown (10YR 6/3) very gravelly sandy loam, brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine and medium roots; 19 percent cobbles and 40 percent gravel; violently effervescent; slightly alkaline; abrupt smooth boundary.
Bw—2 to 5 inches; very pale brown (10YR 7/3) very gravelly sandy loam, pale brown (10YR 6/3) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and medium roots; 18 percent cobbles and 40 percent gravel; violently effervescent; moderately alkaline; clear smooth boundary.
Bk1—5 to 11 inches; very pale brown (10YR 8/3) very gravelly sandy loam, very pale brown (10YR 7/3) moist; weak fine subangular structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and medium roots; 5 percent cobbles and 40 percent gravel; violently effervescent; many fine filaments and threads of calcium carbonate; moderately alkaline; clear smooth boundary.
Bk2—11 to 23 inches; pale brown (10YR 6/3) very gravelly loamy sand, brown (10YR 5/3) moist; weak medium and coarse subangular blocky structure; soft, very friable, nonsticky and nonplastic; few medium roots; 5 percent cobbles and 50 percent gravel; violently effervescent; common fine filaments and threads of calcium carbonate; moderately alkaline; clear smooth boundary.
C1—23 to 30 inches; light brown (7.5YR 6/4) very gravelly loamy sand, yellowish brown (10YR 5/3) moist; massive; soft, friable, nonsticky and nonplastic; few medium roots; 10 percent cobbles and 45 percent gravel; strongly effervescent; moderately alkaline; clear smooth boundary.
C2—30 to 60 inches; light brown (7.5YR 6/4) extremely cobbly loamy sand, brown (7.5YR 5/4) moist; massive; soft, very friable; nonsticky and nonplastic; few medium roots; 50 percent cobbles and 30 percent gravel; strongly effervescent; moderately alkaline.

Range in Characteristics

A horizon
Hue: 10YR
Value: 6 dry and 4 moist
Chroma: 3 dry and moist

B and C horizons
Hue: 10YR or 7.5YR
Value: 4 to 8 dry and 5 to 7 moist
Texture: very gravelly sand, extremely cobbly loamy sand, or very gravelly loamy sand. Some pedons may have horizons of very gravelly sandy loam above the C horizons.

Charo Series

Map unit: 405
Depth class: moderately deep
Drainage class: well drained
Landform: hills, mesas, and ridges
Parent material: eolian material and residuum derived from basalt
Elevation: 8,100 to 8,300 feet (2,469 to 2,530 meters)
Slope: 1 to 5 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Fine, mixed Typic Argiborolls

Typical Pedon

Charo very cobbly loam, in an area of mapping unit 405, Charo complex, 1 to 5 percent slopes; Sandoval County; Laguna Seca Quadrangle; about one mile west of Laguna Seca; unsectionized; NAD 27; UTM 13—02 91 297 E—39 20 794 N.

A—0 to 5 inches; very dark grayish brown (10YR 3/2) cobbly loam, very dark brown (10YR 2/2) moist; moderate medium granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and many medium roots; 2 percent stones, 15 percent cobbles and 15 percent gravel; neutral; clear smooth boundary.
Bt1—5 to 12 inches; reddish brown (5YR 4/3) clay, dark reddish brown (5YR 3/3) moist; weak medium angular blocky structure; hard, firm, sticky and plastic; many fine roots and common very fine roots; few fine tubular pores; few thin dark reddish gray (5YR 4/2) clay films on faces of peds and in pores; neutral; clear smooth boundary.
Bt2—12 to 15 inches; reddish brown (5YR 4/3) clay, dark reddish brown (5YR 3/3) moist; moderate medium and coarse angular blocky structure; hard, firm, sticky and plastic; many very fine roots; common, moderately thick, dark reddish gray (10YR 4/2), clay films on faces of peds; neutral; gradual wavy boundary.
Bt3—15 to 25 inches; reddish brown (5YR 4/4) clay, dark reddish brown (5YR 3/4) moist; weak coarse angular blocky structure; very hard, very firm, very sticky and very plastic; few very fine roots; few fine and few medium pores; few thin clay films on faces of peds, in pores, and on coarse fragments; 5 percent cobbles and 5 percent gravel; slightly alkaline; gradual wavy boundary.
C—25 to 28 inches; reddish brown (5YR 4/4) and dark reddish gray (5YR 4/2) clay, dark reddish brown (5YR 3/4) and (5YR 3/2) moist; massive; very hard, very firm, very sticky and very plastic; few very fine and fine pores; 10 percent cobbles and 10 percent gravel; slightly alkaline; abrupt wavy boundary.
R—28 inches; hard basalt.

Range in Characteristics

Particle-size control section: 35 to 60 percent clay
Depth to bedrock: 20 to 40 inches

A horizon
Hue: 7.5YR or 10YR
Chroma: 2 or 3
Texture: loam, cobbly loam or very cobbly loam

Bt horizon
Value: 4 or 5 dry, 3 or 4 moist
Chroma: 3 to 6
Texture: clay loam or clay

Note: C horizons occur in some pedons.

Clovis Series

Map units: 1, 2, 143 ,211
Depth class: very deep
Drainage class: well drained
Landform: fan terraces, mesas, and plains
Parent material: eolian material and slope alluvium derived from sandstone and shale
Elevation: 5,500 to 7,300 feet (1,676 to 2,225 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Haplargids

Typical Pedon

Clovis fine sandy loam, in an area of mapping unit 143, Clovis fine sandy loam, 1 to 4 percent slopes; Sandoval County; Arroyo de las Calabacillas Quadrangle; about 24 miles northwest of Rio Rancho at the far northwest corner of the west mesa; 1,600 feet west and 2,000 feet north of the southeast corner of sec. 17, T. 13 N., R. 1 E. NAD 83, UTM 13—03 31 377 E—39 13 673 N.

A—0 to 3 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and few medium roots; slightly alkaline; abrupt wavy boundary.
Bt1—3 to 7 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; medium and coarse subangular blocky structure; hard, friable, sticky and plastic; common fine and few medium roots; many thin clay films on sand grains; moderately alkaline; clear smooth boundary.
Bt2—7 to 12 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; weak coarse subangular blocky structure; hard, friable, sticky and plastic; few fine roots; many thin clay films on sand grains; moderate alkaline; gradual wavy boundary.
Bt3—12 to 22 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; weak medium subangular blocky structure; hard, friable, sticky and plastic; few fine roots; many thin clay films on sand grains; moderately alkaline; clear wavy boundary.
Bk1—22 to 34 inches; light brown (7.5YR 6/4) sandy clay loam, brown (7.5YR 5/4) moist; weak coarse prismatic structure; very hard, firm, sticky and plastic; violently effervescent; common fine filaments and threads of calcium carbonate; moderately alkaline; diffuse wavy boundary.
Bk2—34 to 60 inches; reddish yellow (7.5YR 6/6) sandy clay loam, brown (7.5YR 5/4) moist; weak coarse prismatic structure; very hard, firm, sticky and plastic; violently effervescent; common medium irregular soft masses of calcium carbonate; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent
Content of rock fragments: 0 to 15 percent stones, cobbles, or gravel

A horizon
Hue: 5YR, 7.5YR, or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 6 dry, 2 to 4 moist
Texture: fine sandy loam or loam

BA, Bt, Btk horizons
Hue: 2.5YR, 5YR, or 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 4 or 6
Texture: sandy clay loam or clay loam

Bk horizon
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 5 to 7 moist
Chroma: 2 to 6
Texture: fine sandy loam or sandy clay loam

Cochiti Series

Map units: 104, 353
Depth class: very deep
Drainage class: well drained
Landform: fan terrace, hills, mesas, plains, and stream terraces
Parent material: gravelly alluvium
Elevation: 5,300 to 7,000 feet (1,615 to 2,134 meters)
Slope: 3 to 40 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Clayey-skeletal, mixed, mesic Aridic Haplustalfs

Typical Pedon

Cochiti gravelly loam, in an area of mapping unit 104, Cochiti-Montecito association, 1 to 30 percent slopes; Sandoval County; Canada Quadrangle; about 10 miles west of Cochiti Pueblo; 1,500 feet east and 300 feet north of the center of sec. 11, T. 16 N., R. 4 E. NAD 83, UTM 13—03 65 807 E—39 44 031 N.

A—0 to 7 inches; dark yellowish brown (10YR 4/4) gravelly loam, dark brown (10YR 3/3) moist; weak fine granular structure; slightly hard, firm, sticky and plastic; many fine and medium roots; 5 percent cobbles and 15 percent gravel; neutral; clear smooth boundary.

Bt1—7 to 12 inches; reddish brown (5YR 4/3) gravelly clay loam, reddish brown (5YR 4/3) moist; strong medium subangular blocky structure; very hard, firm, very sticky and very plastic; common fine and coarse roots; thick continuous clay films on faces of peds; 5 percent cobbles and 25 percent gravel; slightly acid; clear smooth boundary.

Bt2—12 to 20 inches; reddish brown (5YR 4/4) very gravelly clay, reddish brown (5YR 4/4) moist; strong medium and coarse subangular blocky structure; very hard, firm, very sticky and very plastic; few fine and coarse roots; thick continuous clay

films on faces of peds; 5 percent cobbles and 40 percent gravel; neutral; clear smooth boundary.

Bt3—20 to 29 inches; light reddish brown (5YR 6/4) very gravelly clay loam, reddish brown (5YR 5/4) moist; weak medium subangular blocky structure; hard, firm, sticky and plastic; few fine and coarse roots; thin and continuous clay films on faces of peds; 5 percent cobbles and 40 percent gravel; neutral; clear smooth boundary.

C—29 to 60 inches; light reddish brown (5YR 6/4) very gravelly sandy loam, reddish brown (5YR 5/4) moist; massive; loose, nonsticky and nonplastic; few fine and coarse roots; 5 percent cobbles and 50 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 35 to 45 percent clay
Content of rock fragments: 35 to 50 percent by volume with 5 to 10 percent cobbles and 30 to 40 percent gravel

A horizon
Hue: 7.5YR or 10YR
Value: 4 or 5 dry, 3 or 4 moist
Chroma: 3 or 4
Texture: gravelly loam or extremely gravelly loam

B horizon
Hue: 7.5YR or 5YR
Value: 4 to 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: very gravelly clay or very gravelly clay loam

2C horizon
Hue: 7.5YR or 5YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 to 6
Texture: very gravelly loamy sand or very gravelly sandy loam

Cosey Series

Map units: 304, 311
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: slope alluvium and colluvium derived from rhyolite
Elevation: 8,600 to 9,200 feet (2,621 to 2,804 meters)
Slope: 2 to 20 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed Typic Paleborolls

Typical Pedon

Cosey silt loam, in an area of mapping unit 304, Cosey-Jarmillo association, 2 to 20 percent slopes; Sandoval County; Valle Toledo Quadrangle; about 13 miles northeast of La Cueva, 300 feet south of the pipeline, and 2 miles southeast of road junction at west end of Toledo Valley, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 67 849 E—39 78 865 N.

A1—0 to 9 inches; dark grayish brown (10YR 4/2) silt loam, black (10YR 2/1) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and very fine roots; slightly acid; clear smooth boundary.
A2—9 to 15 inches; grayish brown (10YR 5/2) silt loam, very dark brown (10YR 2/2) moist; moderate coarse granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots; slightly acid; clear smooth boundary.
BA—15 to 28 inches; very pale brown (10YR 7/3) gravelly loam, brown (10YR 4/3) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine and very fine roots; 10 percent cobbles and 20 percent gravel; slightly acid; gradual smooth boundary.
Bt1—28 to 34 inches; very pale brown (10YR 7/3) very gravelly sandy clay loam, brown (10YR 4/3) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine and very fine roots; common moderately thick clay films on faces of peds; 10 percent cobbles and 50 percent gravel; slightly acid; gradual smooth boundary.
Bt2—34 to 60 inches; light brown (7.5YR 6/4) crushed, extremely cobbly clay loam, dark brown (7.5YR 4/4) moist; strata of very pale brown (10YR 7/3) silty clay loam and brownish yellow (10YR 6/6) sandy loam; weak medium subangular blocky structure; hard, firm, sticky and plastic; continuous thick clay films on faces of peds; 40 percent cobbles and 30 percent gravel; slightly acid.

Range in Characteristics

Particle-size control section: 27 to 35 percent clay
Depth to argillic horizon: 22 to 35 inches

A horizon
Value: 3, 4 or 5 dry, 2 or 3 moist
Chroma: 1 to 3
Texture: loam, silt loam

BA horizon
Value: 6 to 8 dry, 4 to 6 moist
Chroma: 2 or 3
Texture: gravelly sandy loam, gravelly fine sandy loam, and gravelly loam

Bt horizon
Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 3 or 4
Texture: very gravelly sandy clay loam or extremely cobbly clay loam

Councelor Series

Map units: 180, 270
Depth class: very deep
Drainage class: well drained
Landform: stream terraces, fan terraces, valley floors, and valley sides
Parent material: eolian material and stream alluvium derived from sandstone and shale
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 1 to 30 percent

Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Coarse-loamy, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

Councelor fine sandy loam, in an area of mapping unit 180, Councelor-Eslendo-Mespun complex, 5 to 30 percent slopes; Sandoval County; Galisteo SE Quadrangle; about 15 miles southwest of Councelor; 1,500 feet north and 1,500 feet east of the southwest corner of sec. 6, T. 21 N., R. 6 W. NAD 83, UTM 13—02 73 616 E—39 95 265 N.

A—0 to 2 inches; pale brown (10YR 6/3) fine sandy loam, brown (10YR 5/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; few very fine and fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—2 to 7 inches; pale brown (10YR 6/3) fine sandy loam, dark brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; few very fine and fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C2—7 to 37 inches; pale brown (10YR 6/3) fine sandy loam, yellowish brown (10YR 5/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; few very fine and fine roots; slightly effervescent; moderately alkaline; gradual smooth boundary.
C3—37 to 40 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; massive; hard, firm, sticky and plastic; few fine and very fine roots; strongly effervescent; very few fine irregular soft masses of calcium carbonate; moderately alkaline; clear smooth boundary.
C4—40 to 60 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; soft, friable, slightly sticky and slightly plastic; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 8 to 18 percent clay

A horizon
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 3 to 5 moist
Chroma: 2 to 4

C horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 4 dry, 2 to 6 moist
Texture: fine sandy loam, sandy loam, or clay loam

Note: The C horizon contains thin strata of loamy sand, loamy fine sand, and sandy clay loam in some pedons.

Cucho Series

Map units: 397, 398, 399
Depth class: moderately deep
Drainage class: well drained
Landform: cuestas and fan terraces

Parent material: colluvium derived from shale
Elevation: 5,900 to 7,200 feet (1,798 to 2,195 meters)
Slope: 15 to 70 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-silty, mixed, calcareous, mesic Typic Ustorthents

Typical Pedon

Cucho very gravelly clay loam in an area of mapping unit 397, Rock outcrop-Cucho-Vessilla complex, 25 to 70 percent slopes; Sandoval County; Holy Ghost Spring Quadrangle; 1.5 miles east of state highway 44 and 0.5 miles south of the Jemez-Zia Indian Reservations boundary. unsectionized; NAD 83, UTM 13—03 27 007 E—39 52 487 N.

A—0 to 2 inches; pale yellow (2.5Y 7/4) and very pale brown (10YR 7/4) very gravelly clay loam, light olive brown (2.5Y 5/4) and yellowish brown (10YR 5/4) moist; moderate fine granular structure; slightly hard, friable, sticky and slightly plastic; common fine and few medium roots; 45 percent gravel; slightly effervescent; slightly alkaline; abrupt smooth boundary.
C1—2 to 9 inches; light gray (5Y 7/2) clay loam, light olive gray (5Y 6/2) moist; massive; hard, firm, sticky and plastic; few medium roots; slightly effervescent; neutral; gradual wavy boundary.
C2—9 to 37 inches; pale olive (5Y 6/3) clay loam, olive (5Y 5/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; few medium roots in upper part; 50 percent soft weathered shale fragments at upper boundary grading to 90 percent at lower boundary; matrix slightly effervescent; few medium strongly effervescent irregular soft masses of calcium carbonate; slightly alkaline; gradual wavy boundary.
Cr—37 to 60 inches; fractured shale.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay, less than 15 percent fine sand or coarser
Calcium carbonate equivalent: 1 to 10 percent
Depth to a Cr horizon: 20 to 40 inches

A horizon
Hue: 2.5Y or 10YR
Value: 6 or 7 dry

C horizon
Hue: 5Y or 2.5Y
Value: 6 or 7 dry, 5 or 6 moist
Chroma: 2 to 4
Texture: clay loam or silty clay loam

Cypher Series

Map units: 503, 600, 604
Depth class: shallow
Drainage class: well drained
Landform: mountain slopes and ridges
Parent material: colluvium and residuum derived from rhyolite and tuff

Elevation: 6,500 to 9,000 feet (1,981 to 2,743 meters)
Slope: 15 to 60 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed, frigid Lithic Ustochrepts

Typical Pedon

Cypher very gravelly loam, in an area of mapping unit 604, Cypher-Mirand complex, 15 to 55 percent slopes; Sandoval County; Bear Springs Peak Quadrangle; about 3/4 mile north of the Bear Springs Guard Station in the Canada de Cochiti; unsectionized; NAD 83, UTM 13—03 59 321 E—39 49 884 N.

Oi—0 to 1 inch; slightly decomposed forest litter.
A—1 inch to 5 inches; brown (10YR 5/3) very gravelly loam, very dark grayish brown (10YR 3/2) moist; weak platy structure parting to weak very fine granular; soft, very friable, slightly sticky and nonplastic; many very fine roots; few very fine tubular pores; 10 percent cobbles and 45 percent gravel; slightly acid; clear smooth boundary.
Bw—5 to 12 inches; pale brown (10YR 6/3) very gravelly loam, brown (10YR 4/3) moist; weak medium angular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; many very fine, few fine, and few coarse roots; common very fine tubular pores; 10 percent cobbles and 40 percent gravel; medium acid; clear smooth boundary.
C—12 to 20 inches; light brown (7.5YR 6/4) extremely gravelly sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few very fine, few fine, and few coarse roots; common thin clay films on coarse fragments; 10 percent cobbles and 75 percent gravel; slightly acid; abrupt wavy boundary.
2R—20 inches; rhyolite bedrock.

Range in Characteristics

Particle-size control section: 10 to 25 percent clay
Calcium carbonate equivalent: 0 to 5 percent
Depth to bedrock from mineral surface: 10 to 20 inches

A horizon
Hue: 7.5YR or 10YR
Value: 2 to 5 dry, 2 to 4 moist
Chroma: 2 to 4
Texture: very gravelly loam or very cobbly loam

Bw horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 2 to 4
Texture: very gravelly sandy loam or very gravelly loam

C horizon
Hue: 5YR, 7.5YR or 10YR
Value: 6 or 7 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: extremely gravelly sandy loam or very gravelly loam

Deama Series

Map units: 58, 358
Depth class: very shallow and shallow
Drainage class: well drained
Landform: hills, plateaus, and mesas
Parent material: colluvium derived from limestone
Elevation: 5,800 to 7,000 feet (1,768 to 2,134 meters)
Slope: 10 to 55 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy-skeletal, carbonatic, mesic Lithic Calciustolls

Typical Pedon

Deama very stony silt loam, in an area of mapping unit 58, Deama-El Pedro association, 5 to 30 percent slopes; Sandoval County; Sandia Crest Quadrangle; about .75 mile northwest of La Madera; 1,300 feet west and 1,800 feet south of the northeast corner of sec. 35, T. 12 N., R. 5 E. NAD 83, UTM 13—03 74 645 E—38 98 880 N.

A—0 to 7 inches; dark brown (7.5YR 3/2) very stony silt loam, very dark brown (7.5YR 2/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many medium and coarse roots; 20 percent stones, 10 percent cobbles, and 10 percent gravel; strongly effervescent; slightly alkaline; clear smooth boundary.
Bk—7 to 14 inches; pinkish gray (7.5YR 7/2) very cobbly silt loam, dark brown (7.5YR 3/2) moist; weak fine subangular blocky structure; slightly hard, very friable, sticky and plastic; many coarse roots; 7 percent stones, 15 percent cobbles, and 20 percent gravel; violently effervescent; many thin filaments of calcium carbonate; moderately alkaline; abrupt smooth boundary.
2R—14 inches; limestone.

Range in Characteristics

Particle-size control section: 18 to 27 percent clay
Calcium carbonate equivalent: 40 to 60 percent in the particle-size control section
Depth to bedrock: 7 to 20 inches

A horizon
Hue: 5YR to 10YR
Value: 3 to 6 dry, 2 to 4 moist
Chroma: 2 or 3, dry or moist
Texture: very gravelly loam or very stony silt loam

Bk horizon
Hue: 5YR to 10YR
Value: 4 to 8 dry, 3 to 7 moist
Chroma: 2 to 4, dry or moist
Texture: very gravelly loam or very cobbly silt loam

Doakum Series

Map unit: 150
Depth class: very deep
Drainage class: well drained
Landform: bajadas, dipslopes on cuestas, plateaus, drainageways, and hills
Parent material: eolian material and slope alluvium derived from sandstone and shale
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 0 to 5 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, mesic Ustalfic Haplargids

Typical Pedon

Doakum fine sandy loam, in an area of mapping unit 150, Doakum-Betonnie fine sandy loams, 0 to 8 percent slopes; Sandoval County; Mule Dam Quadrangle; about 8 miles southwest of Councelor, 800 feet south and 1,400 feet west of the northeast corner of sec. 29, T. 22 N., R. 6 W. NAD 83, UTM 13—02 76 101 E—39 99 272 N.

A—0 to 5 inches; light yellowish brown (10YR 6/4) fine sandy loam, yellowish brown (10YR 5/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few very fine roots; few very fine continuous pores; moderately alkaline; clear smooth boundary.

Bt1—5 to 11 inches; brown (7.5YR 5/4) clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common fine and medium roots; common very fine and fine continuous pores; few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

Bt2—11 to 17 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; very hard, firm, slightly sticky and slight plastic; common fine and medium roots; common very fine and fine continuous pores; few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

Bk1—17 to 24 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; weak fine subangular blocky structure; hard, firm, slightly sticky and plastic; common very fine roots; few very fine and fine continuous pores; strongly effervescent; few medium irregular soft masses of calcium carbonate; strongly alkaline; clear smooth boundary.

Bk2—24 to 31 inches; very pale brown (10YR 7/3) clay loam, pale brown (10YR 6/3) moist; massive; hard, firm, sticky and plastic; few very fine roots; violently effervescent; few medium irregular soft masses of calcium carbonate; strongly alkaline; clear smooth boundary.

Bk3—31 to 44 inches; very pale brown (10YR 7/3) loam, pale brown (10YR 6/3) moist; massive; very hard, firm, slightly sticky and slightly plastic; few very fine roots; violently effervescent; few medium soft masses and seams of calcium carbonate; strongly alkaline; clear gradual boundary.

C—44 to 60 inches; very pale brown (10YR 7/4) loam, light yellowish brown (10YR 6/4) moist; massive; soft, very friable, slightly sticky and slightly plastic; violently effervescent; strongly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Salinity: EC of 2 to 8

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4

Bt or Btk horizons
Hue: 5YR or 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 6 dry and moist
Texture: loam, sandy clay loam, or clay loam

Bk horizon
Hue: 5YR, 7.5YR or 10YR
Value: 4 to 8 dry, 4 to 7 moist
Chroma: 2 to 6
Texture: loam, fine sandy loam, sandy clay loam, or clay loam
Calcium carbonate equivalent: less than 15 percent

C horizon
Hue: 10YR or 7.5YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: loam, very fine sandy loam, fine sandy loam, or loamy fine sand

El Rancho Series

Map units: 95, 97
Depth class: very deep
Drainage class: well drained
Landform: stream terraces
Parent material: stream alluvium derived from mixed sources
Elevation: 5,300 to 5,500 feet (1,615 to 1,676 meters)
Slope: 0 to 2 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

El Rancho loam, in an area of mapping unit 95, El Rancho loam, 0 to 2 percent slopes; Sandoval County; San Ysidro Quadrangle; the north edge of San Ysidro; unsectionized; NAD 83, UTM 13—03 39 479 E—39 36 553 N.

Ap—0 to 5 inches; reddish brown (5YR 5/3) loam, dark reddish brown (5YR 3/4) moist; weak fine granular structure; hard, friable, slightly sticky and slightly plastic; common fine and medium roots; violently effervescent; moderately alkaline; abrupt smooth boundary.
C1—5 to 20 inches; reddish brown (5YR 5/4) sandy clay loam, reddish brown (5YR 4/4) moist; weak fine subangular blocky structure; hard, firm, sticky and plastic; common fine and very fine roots; violently effervescent; moderately alkaline; clear smooth boundary.
C2—20 to 38 inches; reddish brown (5YR 5/4) sandy clay loam, reddish brown (5YR 4/4) moist; massive; hard, firm, sticky and plastic; few fine and very fine roots; violently effervescent; moderately alkaline; clear smooth boundary.

2C3—38 to 60 inches; light brown (7.5YR 6/4) sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; violently effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 10 to 27 percent clay and greater than 50 percent sand

A horizon
Hue: 5YR or 7.5YR
Value: 5 or 6 dry, 3 or 4 moist
Chroma: 3 or 4
Texture: loam or clay loam

C horizon
Hue: 5YR or 7.5YR
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: sandy loam or sandy clay loam

Elpedro Series

Map units: 58, 317, 358
Depth class: very deep
Drainage class: well drained
Landform: benches, fan piedmonts, hills, mesas, and valley sides
Parent material: eolian material and colluvium derived from limestone
Elevation: 5,700 to 7,000 feet (1,737 to 2,134 meters)
Slope: 1 to 40 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-silty, mixed, mesic Aridic Haplustalfs

Typical Pedon

Elpedro loam, in an area of mapping unit 58, Deama-Elpedro association, 5 to 30 percent slopes; Sandoval County; Sandia Park Quadrangle; about 2 miles northeast of La Madera; unsectionized; NAD 83, UTM 13—03 76 147 E—39 00 367 N.

A—0 to 5 inches; brown (7.5YR 4/4) loam, dark brown (7.5YR 3/3) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and medium roots; slightly alkaline; abrupt smooth boundary.
Bt1—5 to 12 inches; dark brown (7.5YR 3/4) silty clay loam, dark brown (7.5YR 3/4) moist; weak medium subangular blocky structure; hard, friable, sticky and plastic; many fine and coarse roots; few thin discontinuous clay films on faces of peds; slightly alkaline; clear smooth boundary.
Bt2—12 to 19 inches; brown (7.5YR 5/4) silty clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, friable, sticky and plastic; few very fine and coarse roots; thin discontinuous clay films on faces of peds; slightly effervescent; moderately alkaline; clear smooth boundary.
Bt3—19 to 25 inches; brown (7.5YR 5/4) silty clay loam, brown (7.5YR 4/4) moist; moderate fine and medium prismatic structure parting to moderate fine subangular blocky; hard, friable, sticky and plastic; few very fine roots; thick continuous clay films on faces of peds; slightly effervescent; few seams and filaments of calcium carbonate; moderately alkaline; clear smooth boundary.

Btk1—25 to 36 inches; brown (7.5YR 5/4) silty clay loam, brown (7.5R 4/4) moist; strong fine prismatic structure parting to strong fine and medium subangular blocky; hard, friable, sticky and plastic; few very fine roots; thick continuous clay films on faces of peds; strongly effervescent; thin filaments of calcium carbonates on peds; slightly alkaline; clear smooth boundary.
Btk2—36 to 45 inches; brown (7.5YR 5/4) silt loam, brown (7.5YR 4/4) moist; weak medium prismatic structure; hard, friable, sticky and plastic; few very fine roots; thin continuous clay films on faces of peds; strongly effervescent; seams and filaments of calcium carbonate on faces of peds; slightly alkaline; clear smooth boundary.
Btk3—45 to 60 inches; brown (7.5YR 5/4) loam, brown (7.5YR 4/4) moist; weak coarse prismatic structure; hard, friable, sticky and plastic; few very fine roots; thin discontinuous clay films on faces of peds; strongly effervescent; few calcium carbonate accumulations; slightly alkaline.

Range in Characteristics

Particle-size control section: 27 to 35 percent clay
Calcium carbonate equivalent: 0 to 15 percent
Reaction: slightly to moderately alkaline

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: loam or very gravelly loam

Bt and Btk horizons
Hue: 10YR to 5YR
Value: 3 to 6 dry, 4 to 5 moist
Chroma: 3 to 5
Texture: silty clay loam, loam, and silt loam

Bk horizon (when present)
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: loam, silt loam, or silty clay loam

Embudo Series

Map units: 108, 109
Depth class: very deep
Drainage class: well drained
Landform: fan remnants and fan terraces
Parent material: fan alluvium derived from granite
Elevation: 5,000 to 5,600 feet (1,524 to 1,707 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Coarse-loamy, mixed, mesic Typic Camborthids

Typical Pedon

Embudo gravelly sandy loam, in an area of mapping unit 109, Embudo-Tijeras association, 1 to 9 percent slopes; Sandoval County; Alameda Quadrangle; about 1.5 miles east of Interstate Highway 25 and about 1 mile north of the Bernalillo-Sandoval County line; 950 feet east and 2,050 feet south of the northwest corner of sec. 32, T. 12 N., R. 4 E. NAD 83, UTM 13—03 59 192 E—38 99 070 N.

A—0 to 4 inches; brown (10YR 5/3) gravelly sandy loam, dark brown (10YR 4/3) moist; weak fine granular structure; slightly hard, friable, nonsticky and nonplastic; many very fine roots; 20 percent gravel; slightly alkaline; clear wavy boundary.

Bw—4 to 12 inches; pale brown (10YR 6/3) gravelly fine sandy loam; dark yellowish brown (10YR 4/3) moist; weak fine granular structure; slightly hard, friable, nonsticky and nonplastic; common fine roots; 15 percent gravel; slightly alkaline; gradual wavy boundary.

Bk1—12 to 30 inches; pale brown (10YR 6/4) gravelly coarse sandy loam, yellowish brown (10YR 5/4) moist; massive; hard, friable, nonsticky and nonplastic; few fine roots; 20 percent gravel; slightly effervescent with few medium rounded soft masses of calcium carbonate; moderately alkaline; gradual wavy boundary.

2Bk2—30 to 60 inches; pale brown (10YR 6/4) gravelly loamy coarse sand, yellowish brown (10YR 5/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; 30 percent gravel; slightly effervescent; few fine rounded soft masses of calcium carbonate; moderately alkaline.

Range in Characteristics

Particle-size control section: 5 to 15 percent clay

A and Bw horizons
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 2 to 4

Bk horizon
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 2 to 6
- *Texture:* gravelly coarse sandy loam and sandy loam

2Bk horizon
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 2 to 6
- *Content of rock fragments:* 10 to 70 percent gravel
- *Texture:* gravelly loamy coarse sand or loamy sand
- *Depth to sandy layer:* 18 to 30 inches

Eslendo Series

Map unit: 180
Depth class: very shallow to shallow
Drainage class: well drained
Landform: ridges
Parent material: residuum derived from shale
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 5 to 30 percent
Climatic data:
- *Mean annual precipitation:* 10 to 13 inches (254 to 330 millimeters)
- *Mean annual air temperature:* 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
- *Frost-free period:* 110 to 130 days

Taxonomic class: Loamy, mixed, calcareous, mesic, shallow Ustic Torriorthents

Typical Pedon

Eslendo clay loam, in an area of mapping unit 180, Councelor-Eslendo-Mespun complex, 5 to 30 percent slopes; Galisteo SE Quadrangle; about 16 miles south of Galisteo; 1,760 feet south and 2,400 feet west of the northeast corner of sec. 29, T. 21 N., R. 7 W. NAD 83, UTM 13—02 65 871 E—39 89 619 N.

A—0 to 3 inches; light brownish gray (2.5Y 6/2) clay loam, grayish brown (2.5Y 5/2) moist; weak fine granular structure; hard, firm, sticky and plastic; few very fine and fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C—3 to 10 inches; light yellowish brown (2.5Y 6/4) clay loam, light olive brown (2.5Y 5/4) moist; massive; hard, firm, sticky and plastic; few fine roots; few fine pores; slightly effervescent; disseminated calcium carbonate; moderately alkaline; abrupt smooth boundary.
Cr—10 inches; soft shale.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Soil depth: 4 to 20 inches to soft shale

Espiritu Series

Map units: 325, 345, 346, 353, 398
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes and mesas
Parent material: slope alluvium and colluvium derived from mixed sources
Elevation: 5,300 to 6,900 feet (1,615 to 2,103 meters)
Slope: 8 to 65 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy-skeletal, mixed, mesic Aridic Haplustalfs

Typical Pedon

Espiritu very gravelly fine sandy loam, in an area of mapping unit 345, Espiritu-Bamac association, 15 to 55 percent slopes; Sandoval County; Loma Creston Quadrangle; 11 miles northeast of the Zia Pueblo; unsectionized; NAD 83, UTM 13—03 60 501 E—39 35 768 N.

A—0 to 6 inches; brown (10YR 5/3) very gravelly fine sandy loam, dark brown (10YR 4/3) moist; weak very fine granular structure; soft, very friable, nonsticky and slightly plastic; many fine and common medium roots; 10 percent cobbles and 30 percent gravel; slightly alkaline; clear smooth boundary.
Bt1—6 to 15 inches; brown (7.5YR 5/4) very gravelly sandy clay loam, dark brown (7.5YR 3/4) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; common fine roots; few fine tubular pores; common thin clay films on faces of peds; 10 percent cobbles and 30 percent gravel; slightly alkaline; clear wavy boundary.
Bt2—15 to 22 inches; light brown (7.5YR 6/4) very gravelly sandy clay loam, brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; hard, friable, slightly sticky and slightly plastic; few fine roots; few fine tubular pores; few thin

clay films of faces of peds; 10 percent cobbles and 35 percent gravel; slightly alkaline; gradual wavy boundary.

Bk1—22 to 29 inches; pale brown (10YR 6/3) very cobbly sandy clay loam, brown (10YR 4/3) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine tubular pores; 25 percent cobbles and 25 percent gravel; strongly effervescent; few medium irregular soft masses of calcium carbonate; slightly alkaline; gradual wavy boundary.

Bk2—29 to 38 inches; pale brown (10YR 6/3) very cobbly sandy clay loam, brown (10YR 4/3) moist; massive; slightly hard, friable, slightly sticky, and slightly plastic; 25 percent cobbles and 25 percent gravel; strongly effervescent; few medium irregular soft masses of calcium carbonate; slightly alkaline; clear wavy boundary.

2C1—38 to 46 inches; strong brown (7.5YR 5/6) fine sandy loam, brown (7.5YR 4/4) moist; massive; hard, friable, slightly sticky and slightly plastic; strongly effervescent; slightly alkaline; gradual wavy boundary.

3C2—46 to 60 inches; reddish yellow (7.5YR 6/6) very gravelly sandy loam, strong brown (7.5YR 4/6) moist; massive; hard, friable, nonsticky and nonplastic; 3 percent cobbles and 35 percent gravel; strongly effervescent; slightly alkaline.

Range in Characteristics

Particle-size control section: 15 to 35 percent clay

A horizon
- *Hue:* 7.5YR or 10YR
- *Value:* 4 or 5 dry, 3 or 4 moist
- *Chroma:* 2 to 4
- *Texture:* extremely cobbly sandy loam, very gravelly loam, and very gravelly fine sandy loam

Bt horizon
- *Hue:* 5YR, 7.5YR or 10YR
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 3 to 6

Bk horizon
- *Hue:* 5YR, 7.5YR or 10YR
- *Value:* 5 or 6 dry, 4 or 5 moist
- *Chroma:* 3 to 6
- *Texture:* extremely gravelly loamy sand, extremely gravelly sandy loam, very gravelly loam, and very cobbly sandy clay loam

C horizons (when present)
- *Hue:* 5YR, 7.5YR or 10YR
- *Value:* 5 or 6 dry, 4 or 5 moist
- *Chroma:* 3 to 6
- *Texture:* very gravelly sandy loam, extremely gravelly sandy loam, fine sandy loam, or very gravelly loam

Note: In some pedons, the lower C horizons are sand, very gravelly loamy sand, or extremely gravelly loamy sand.

Ess Series

Map unit: 215
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes

Parent material: colluvium derived from rhyolite
Elevation: 9,000 to 11,000 feet (2,743 to 3,353 meters)
Slope: 5 to 45 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed Argic Cryoborolls

Typical Pedon

Ess very cobbly sandy loam, in an area of mapping unit 215, Ess-Rock outcrop complex, 5 to 45 percent slopes; Sandoval County; Valle Toledo Quadrangle; about 100 yards west of ski lift near Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 73 642 E—39 71 846 N.

A1—0 to 7 inches; very dark gray (10YR 3/1) very cobbly sandy loam, very dark brown (10YR 2/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine and medium roots; 5 percent stones, 35 percent cobbles and 10 percent gravel; neutral; clear smooth boundary.
A2—7 to 15 inches; very dark gray (10YR 3/1) very cobbly sandy loam, very dark brown (10YR 2/2) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; common fine roots; 5 percent stones, 30 percent cobbles and 10 percent gravel; neutral; clear smooth boundary.
Bt—15 to 29 inches; strong brown (7.5YR 5/6) very cobbly sandy clay loam, dark brown (7.5YR 3/4) moist; weak fine subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; few very fine roots; few thin discontinuous clay films on rock fragments; 10 percent stones, 30 percent cobbles and 10 percent gravel; neutral; gradual wavy boundary.
C—29 to 60 inches; very pale brown (10YR 7/3) very cobbly loam, brown (10YR 4/3) moist; massive; soft, very friable, nonsticky and nonplastic; few very fine roots; 5 percent stones, 20 percent cobbles, and 30 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 20 to 30 percent clay

A horizon
Hue: 7.5YR, 10YR
Value: 3 to 5 dry, and 2 or 3 moist
Chroma: 1 to 3

B horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6

Flugle Series

Map unit: 307
Depth class: very deep
Drainage class: well drained
Landform: cuestas, fan terraces, hills, ridges, and valley sides
Parent material: eolian material and fan alluvium derived from sandstone and shale
Elevation: 5,600 to 6,100 feet (1,707 to 1,859 meters)
Slope: 1 to 5 percent

Climatic data:

Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, mesic Aridic Haplustalfs

Typical Pedon

Flugle loam, in an area of mapping unit 307, Flugle-Waumac complex, 1 to 8 percent slopes; Sandoval County; Jemez Pueblo Quadrangle; about 3 miles northeast of Zia Pueblo; 630 feet west and 750 feet south of the northeast corner of sec. 13, T. 15 N., R. 2 E. NAD 83, UTM 13—03 48 170 E—39 33 463 N.

A—0 to 3 inches; yellowish brown (10YR 5/4) loam, dark brown (10YR 4/3) moist; weak thin platy structure; soft, very friable, nonsticky and nonplastic; many very fine roots; neutral; abrupt smooth boundary.

Bt—3 to 7 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; moderate fine and medium subangular blocky structure; slightly hard, friable, sticky and plastic; many very fine roots; many very fine tubular pores; common moderately thick clay films on faces of peds; neutral; clear smooth boundary.

Btk1—7 to 12 inches; light brown (7.5YR 6/4) sandy clay loam, brown (7.5YR 5/4) moist; moderate fine and medium subangular blocky structure; slightly hard, friable, sticky and plastic; common very fine roots; many very fine tubular pores; many moderately thick clay films on faces of peds; strongly effervescent; common fine irregular filaments of calcium carbonate; slightly alkaline; clear smooth boundary.

Btk2—12 to 19 inches; light brown (7.5YR 6/4) sandy clay loam, brown (7.5YR 5/4) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few very fine roots; many very fine tubular pores; few thin clay films on faces of peds; strongly effervescent; few fine calcium carbonate accumulations; slightly alkaline; clear smooth boundary.

Bk—19 to 60 inches; pink (7.5YR 7/4) fine sandy loam, light brown (7.5YR 6/4) moist; massive; slightly hard, very friable, nonsticky and nonplastic; few fine roots; common very fine pores; strongly effervescent; few coarse calcium carbonate accumulations; slightly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay and greater than 35 percent sand

A horizon

Hue: 5YR, 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4

B horizon

Hue: 5YR, 7.5YR or 10YR
Value: 3 to 6 dry, 3 to 5 moist
Chroma: 2 to 6

C or Bk horizon

Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 3 to 6

Fragua Series

Map units: 314, 322
Depth class: deep and very deep
Drainage class: well drained
Landform: fan remnants and dipslopes
Parent material: eolian material and fan alluvium derived from sandstone
Elevation: 5,600 to 7,400 feet (1,707 to 2,256 meters)
Slope: 1 to 70 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Coarse-loamy, mixed, mesic Aridic Haplustalfs

Typical Pedon

Fragua loamy sand, in an area of mapping unit 314, Fragua-Waumac-Royosa complex, 1 to 8 percent slopes; Sandoval County; Jemez Pueblo Quadrangle; 4 miles northeast of Zia Pueblo; 1,310 feet west and 760 feet north of the southeast corner of sec. 7, T. 15 N., R. 3 E. NAD 83, UTM 13—03 49 686 E—39 33 977 N.

A—0 to 3 inches; brown (10YR 5/3) loamy sand, dark brown (10YR 4/3) moist; moderate fine granular structure; soft, very friable, nonsticky and nonplastic; common fine roots; slightly alkaline; clear smooth boundary.
Bt1—3 to 8 inches; brown (7.5YR 5/4) sandy loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and few very fine roots; common thin clay films on faces of peds; slightly alkaline; gradual wavy boundary.
Bt2—8 to 24 inches; brown (7.5YR 5/6) sandy loam, strong brown (7.5YR 4/6) moist; moderate medium subangular blocky structure; hard, friable, nonsticky and nonplastic; few fine roots; few thin clay films on faces of peds; slightly alkaline; clear wavy boundary.
C—24 to 60 inches; brown (7.5YR 5/4) sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few fine roots; slightly alkaline.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay
Depth to bedrock: 40 to more than 60 inches

A horizon
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 3 or 5 moist
Chroma: 3 or 4 dry, 2 to 4 moist
Texture: loamy sand or very cobbly fine sandy loam

Bt horizon
Hue: 5YR to 10YR
Value: 4 or 6 dry, 3 to 5 moist
Chroma: 4 to 6
Texture: sandy loam, fine sandy loam, or very fine sandy loam

Bk or C horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 3 to 6 moist
Chroma: 4 to 8 dry, 4 or 6 moist
Texture: loamy fine sand, fine sandy loam, or sandy loam

Frijoles Series

Map unit: 185
Depth class: very deep
Drainage class: well drained
Landform: summits of mesas
Parent material: eolian material and alluvium derived from pumice
Elevation: 6,000 to 7,000 feet (1,829 to 2,134 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy-skeletal over fragmental, mixed, mesic Aridic Haplustalfs

Typical Pedon

Frijoles very fine sandy loam, in an area of mapping unit 185, Frijoles very fine sandy loam, 1 to 8 percent slopes; Los Alamos County; Frijoles Quadrangle; unsectionized; NAD 83, UTM 13—03 83 492 E—39 62 785 N.

A—0 to 3 inches; brown (10YR 5/3) very fine sandy loam, dark brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine roots; many fine vesicular pores; neutral; abrupt smooth boundary.
Bt1—3 to 8 inches; brown (7.5YR 4/4) very gravelly clay loam, dark brown (7.5YR 3/4) moist; moderate fine subangular blocky structure; hard, firm, sticky and plastic; many fine roots; many fine vesicular pores; thin discontinuous clay films on faces of peds; 35 percent fine pumice gravel; neutral; clear smooth boundary.
Bt2—8 to 13 inches; brown (7.5YR 5/4) very gravelly clay loam, dark brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; hard, friable, sticky and plastic; many fine roots; many fine vesicular pores; thin discontinuous clay films on faces of peds; 45 percent fine pumice gravel; neutral clear smooth boundary.
2C1—13 to 20 inches; pinkish gray (7.5YR 7/2) extremely gravelly sandy loam, pinkish gray (7.5YR 6/2) moist; weak fine subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; few fine roots; 70 percent pumice gravel; neutral; clear wavy boundary.
3C2—20 to 60 inches; pinkish white (7.5YR 8/2) pumice gravel, pinkish gray (7.5YR 7/2) moist; few fine roots; strong brown (7.5YR 5/6) lamella; few fine thin discontinuous clay films within the lamella.

Range in Characteristics

Particle-size control section: 27 to 35 percent clay
Depth to contrasting particle-size: 15 to 30 inches

A horizon
Value: 4 or 5 dry, 3 or 4 moist
Chroma: 2 or 3

Bt horizon
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 4 or 6

Galisteo Series

Map units: 92, 130, 226
Depth class: very deep
Drainage class: well drained
Landform: stream terraces and alluvial fans
Parent material: stream alluvium derived from mixed sources
Elevation: 5,500 to 7,000 feet (1,676 to 2,134 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 50 to 54 degrees F. (10.0 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

Galisteo silty clay loam, in an area of mapping unit 92, Galisteo silty clay loam, moderately saline, sodic, 0 to 1 percent slopes; Sandoval County; San Ysidro Quadrangle; on the west edge of San Ysidro between old and new highway; unsectionized; NAD 83, UTM 13—03 38 222 E—39 35 960 N.

Ap—O to 12 inches; reddish brown (2.5YR 4/4) silty clay loam, dark reddish brown (2.5YR 3/4) moist; massive; hard, firm, very sticky and very plastic; common fine and medium roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C—12 to 60 inches; reddish brown (2.5YR 4/4) clay, dark reddish brown (2.5YR 3/4) moist; massive; very hard, extremely firm, very sticky and very plastic; few fine and very fine roots; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 35 to 59 percent clay
Salinity: EC of 8 to 16
Sodicity: SAR of 5 to 30

A horizon
Hue: 2.5YR to 7.5YR
Value: 4 to 6 dry and 3 to 5 moist
Chroma: 2 to 4 dry and moist
Texture: loam, clay loam, and silty clay loam

C horizon
Hue: 2.5YR to 7.5YR
Value: 4 to 6 dry and 3 to 5 moist
Chroma: 2 to 4 dry and moist
Texture: silty clay loam and clay

Gilco Series

Map units: 20, 25, 421, 423, 823
Depth class: very deep
Drainage class: moderately well drained
Landform: flood plains
Parent material: stream alluvium derived from mixed sources
Elevation: 5,000 to 6,000 feet (1,524 to 1,829 meters)
Slope: 0 to 4 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Coarse-loamy, mixed, calcareous, mesic Typic Torrifluvents

Typical Pedon

Gilco loam, in an area of mapping unit 25, Gilco loam, 0 to 1 percent slope; Sandoval County; Santo Domingo Pueblo Quadrangle; in Pena Blanca area; unsectionized; NAD 83, UTM 13—03 78 027 E—39 35 759 N.

Ap—0 to 4 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and very fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C1—4 to 34 inches; light yellowish brown (10YR 6/4) stratified silt loam, loam, and fine sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; common fine and very fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C2—34 to 60 inches; light yellowish brown (10YR 6/4) stratified loam and fine sandy loam, dark yellowish brown (1OYR 4/4) moist; massive; hard, firm, slightly sticky and slightly plastic; few fine roots; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay
Salinity: EC of 0 to 16
Sodium: SAR less than 13

A Horizon
Hue: 10YR or 7.5YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: loam or clay loam

C Horizon
Hue: 10YR or 7.5YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: very fine sandy loam, fine sandy loam, silt loam, or loam

Note: The Gilco soil in mapping unit 421 Gilco loam, moderately saline, sodic, 0 to 1 percent slopes, has higher sodium absorption ratios than is typical for the Gilco Series and is considered a taxadjunct to the series.

Grieta Series

Map units: 142, 145
Depth class: very deep
Drainage class: well drained
Landform: fan remnants, mesas, plateaus, and ridges
Parent material: eolian material and fan alluvium derived from mixed sources
Elevation: 5,000 to 6,000 feet (1,524 to 1,829 meters)
Slope: 1 to 5 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Fine-loamy, mixed, mesic Typic Haplargids

Typical Pedon

Grieta loamy fine sand, in an area of mapping unit 145, Grieta-Sheppard loamy fine sands, 2 to 9 percent slopes; Sandoval County; Arroyo de las Calabacillas Quadrangle; about 6 miles northwest of Rio Rancho and 450 feet north and 720 feet east of the southwest corner of sec. 20, T. 13 N., R. 2 E. NAD 83, UTM 13—03 40 104 E—39 11 426 N.

A—0 to 7 inches; brown (10YR 5/3) loamy fine sand, dark brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few fine and few very fine roots; slightly alkaline; clear smooth boundary.

Bt1—7 to 14 inches; yellowish brown (7.5YR 5/4) sandy clay loam, dark yellowish brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, friable, sticky and plastic; common fine and common very fine roots; common thin clay films on faces of peds; moderately alkaline; clear smooth boundary.

Bt2—14 to 21 inches; pale brown (10YR 6/3) sandy clay loam, brown (10YR 4/3) moist; weak medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; common fine very fine roots; 5 percent gravel; slightly effervescent; moderately alkaline; clear smooth boundary.

Bk1—21 to 38 inches; light yellowish brown (10YR 6/4) coarse sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, slightly sticky and nonplastic; 10 percent gravel; strongly effervescent; few fine irregularly shaped masses and thin coatings of calcium carbonate on undersides of coarse fragments; moderately alkaline; clear smooth boundary.

Bk2—38 to 50 inches; white (10YR 8/2) coarse sandy loam, yellowish brown (10YR 5/4) moist; massive; hard, friable, slightly sticky and nonplastic; 2 percent gravel; violently effervescent; calcium carbonate as coatings on sand grains and as common fine irregularly shaped masses; moderately alkaline; gradual smooth boundary.

Bk3—50 to 60 inches; very pale brown (10YR 7/4) coarse sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; 3 percent gravel; strongly effervescent; calcium carbonate as few fine irregularly shaped masses; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 t0 35 percent clay and greater than 35 percent sand
Depth to calcic horizon: 20 to 40 inches

A horizon
Hue: 5YR, 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: loamy fine sand or fine sandy loam

Bt horizon
Hue: 5YR, 7.5YR or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 3 to 6
Texture: fine sandy loam or sandy clay loam

Bk horizon
Hue: 7.5YR or 10YR
Value: 5 to 8 dry, 4 to 6 moist
Chroma: 2 to 6
Texture: coarse sandy loam, sandy clay loam or loamy sand

Guaje Series

Map unit: 504
Depth class: very deep
Drainage class: well drained
Landform: basalt-capped mesas, hills, and volcanic cones
Parent material: basalt, volcanic ash, and pumice
Elevation: 6,000 to 7,000 feet (1,829 to 2,134 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Medial-skeletal, mesic Aridic Ustochrepts

Typical Pedon

Guaje gravelly sandy loam, in an area of mapping unit 504, Orejas-Guaje complex, 1 to 15 percent slopes; Sandoval County; Cochiti Dam Quadrangle; about 2 miles east of the Witt Peak recreation area boat dock; unsectionized; NAD 83, UTM 13—03 85 099 E—39 44 994 N.

A—0 to 4 inches; brown (10YR 5/3) gravelly sandy loam, dark brown (10YR 4/3) moist; weak medium granular structure; soft, very friable, slightly sticky and nonplastic; many fine and very fine medium roots; common fine interstitial pores; 20 percent fine pumice gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bw—4 to 12 inches; yellowish brown (10YR 5/4) gravelly sandy loam, dark yellowish brown (10YR 5/4) moist; moderate fine and medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and common very fine roots; few fine interstitial pores; 10 percent cobbles and 20 percent gravel; slightly effervescent; slightly alkaline; clear wavy boundary.

Bk1—12 to 17 inches; very pale brown (10YR 7/4) very gravelly sandy loam, light yellowish brown (10YR 6/4) moist; weak fine and medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; common fine roots; 5 percent cobbles and 55 percent gravel; slightly effervescent; calcium carbonate as common fine soft masses and as coatings on coarse fragments; moderately alkaline; clear wavy boundary.

Bk2—17 to 45 inches; white (N 8/0) and very pale brown (10YR 8/3) extremely gravelly sandy loam, light gray (10YR 7/2) and very pale brown (10YR 7/3) moist; massive; hard, firm, nonsticky and nonplastic; weakly cemented; few fine roots; few fine tubular pores; strongly effervescent; calcium carbonate and siliceous material dominant throughout entire horizon causing 90 percent weak cementation, interrupted only by fractures less than 3 mm wide and less than 4 inches apart; 5 percent cobbles and 60 percent gravel; moderately alkaline; diffuse irregularly boundary.

Bk3—45 to 60 inches; very pale brown (10YR 7/3) very gravelly sandy loam, pale brown (10YR 6/3) moist; massive; soft, very friable, nonsticky and nonplastic; few fine roots; 5 percent cobbles and 50 percent gravel; strongly effervescent; calcium carbonate disseminated throughout and engulfing coarse fragments; moderately alkaline.

Range in Characteristics

Particle-size control section: 5 to 15 percent clay
Depth to the weakly cemented horizon: 12 to 26 inches

A horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 2 to 4

B horizons
Hue: 7.5YR or 10YR
Value: 5 to 8 dry, 4 to 7 moist
Chroma: 0 to 4
Texture: gravelly, very gravelly, and extremely gravelly sandy loams

Hackroy Series

Map units: 21, 162
Depth class: very shallow to shallow
Drainage class: well drained
Landform: summits of mesas and plateaus
Parent material: residuum from tuff
Elevation: 6,000 to 7,200 feet (1,829 to 2,195 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Clayey, mixed, mesic Lithic Haplustalfs

Typical Pedon

Hackroy sandy loam, in an area of mapping unit 162, Hackroy-Nyjack association, 1 to 5 percent slopes; Los Alamos County; White Rock Quadrangle; on the east end of Ancho Canyon Trail; unsectionized; NAD 83, UTM 13—03 87 647 E—39 61 208 N.

A—0 to 3 inches; brown (10YR 5/3) sandy loam, brown (10YR 4/3) moist; weak fine subangular blocky structure; hard, friable, nonsticky and nonplastic; many fine roots; common fine tubular pores; slightly alkaline; abrupt smooth boundary.

Bt—3 to 13 inches; reddish brown (5YR 4/4) clay, dark reddish brown (5YR 3/4) moist; moderate fine prismatic structure; hard, firm, sticky and plastic; many fine roots; few very fine tubular pores; 3 percent gravel; continuous clay films on faces of peds; slightly alkaline; abrupt smooth boundary.
2R—13 inches; tuff.

Range in Characteristics

Particle-size control section: 35 to 50 percent clay
Depth to lithic contact: 8 to 20 inches

A horizon
Hue: 7.5YR or 10YR
Value: 4 or 6 dry, 2 to 4 moist
Chroma: 2 to 4

Bt1 horizon
Hue: 7.5YR or 5YR
Value: 3 to 6 dry, 3 or 4 moist
Chroma: 4 or 6, dry or moist

Hagerman Series

Map units: 227, 240
Depth class: moderately deep
Drainage class: well drained
Landform: hills, mesas and ridges
Parent material: eolian material and alluvium derived from sandstone
Elevation: 5,700 to 6,400 feet (1,737 to 1,951 meters)
Slope: 1 to 5 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Haplargids

Typical Pedon

Hagerman fine sandy loam, in an area of mapping unit 240, Penistaja-Hagerman association, 1 to 5 percent slopes; Sandoval County; Cabezon Peak Quadrangle; about 1.5 miles southeast of the Rio Puerco along the Gas Company of New Mexico pipeline; unsectionized; NAD 83, UTM 13—03 13 428 E—39 43 499 N.

A—0 to 2 inches; brown (7.5YR 5/4) fine sandy loam, dark brown (7.5YR 4/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; common medium and many fine roots; moderately alkaline; clear smooth boundary.
Bt—2 to 9 inches; brown (7.5YR 4/4) clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, firm, sticky and plastic; common medium and many fine roots; thin continuous clay films on faces of peds; moderately alkaline; clear smooth boundary.
Btk—9 to 24 inches; light brown (7.5YR 6/4) clay loam, brown (7.5YR 5/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; few medium and many fine roots; few thin clay films on faces of peds; strongly effervescent; few fine accumulations of calcium carbonate; moderately alkaline; clear smooth boundary.
2R—24 inches; sandstone.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Depth to bedrock: 20 to 40 inches

A horizon
Hue: 5YR to 10YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 2 to 6

Bt horizon
Hue: 7.5YR to 2.5YR
Value: 4 to 7 dry or moist
Chroma: 3 to 6

Btk horizon (when present)
Hue: 7.5YR to 2.5YR
Value: 6 to 8 dry, 5 to 8 moist
Chroma: 3 or 4

Harvey Series

Map units: 53, 54, 59, 65
Depth class: very deep
Drainage class: well drained
Landform: ridges, bajadas, mesas, and plateaus
Parent material: eolian material and fan alluvium derived from mixed sources
Elevation: 5,000 to 6,800 feet (1,524 to 2,073 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Calciorthids

Typical Pedon

Harvey loam, in an area of mapping unit 59, Harvey-Ildefonso-La Fonda association, 3 to 15 percent slopes; Sandoval County; Sandia Park Quadrangle; about 1.8 miles west and 50 feet south along pipeline from Highway 14; unsectionized; NAD 83, UTM 13—03 83 907 E—39 00 604 N.

A—0 to 4 inches; pinkish gray (7.5YR 6/2) loam, brown (7.5YR 5/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and very fine roots; violently effervescent; moderately alkaline; abrupt smooth boundary.

Bw—4 to 10 inches; pinkish gray (7.5YR 6/2) loam, brown (7.5YR 5/2) moist, weak fine subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; common fine roots; violently effervescent; moderately alkaline; clear smooth boundary.

Bk1—10 to 18 inches; pinkish gray (7.5YR 7/2) clay loam, pink (7.5YR 7/4) moist; weak fine subangular blocky structure; hard, firm, sticky and plastic; few fine roots; violently effervescent; many filaments and threads of calcium carbonate; moderately alkaline; clear smooth boundary.

Bk2—18 to 41 inches; pink (7.5YR 7/4) clay loam, pink (7.5YR 7/4) moist; weak medium angular blocky structure; hard, firm, sticky and plastic; few fine roots; violently effervescent; common filaments and threads of calcium carbonate; moderately alkaline; gradual smooth boundary.
C—41 to 60 inches; reddish yellow (7.5YR 6/6) sandy clay loam, brown (7.5YR 5/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; violently effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 2.5YR to 10YR
Value: 5 to 7 dry, 3 to 6 moist
Chroma: 2 to 6
Texture: fine sandy loam or loam

Bw horizon (when present)
Hue: 5YR, 7.5YR, or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: fine sandy loam, loam, or clay loam

Bk horizon
Hue: 2.5YR to 10YR
Value: 5 to 8 dry, 4 to 7 moist
Chroma: 0 to 6
Texture: sandy loam, loam, sandy clay loam, or clay loam

Hickman Series

Map unit: 23
Depth class: very deep
Drainage class: well drained
Landform: flood plains and valley floors
Parent material: stream alluvium derived from mixed sources
Elevation: 6,500 to 7,500 feet (1,981 to 2,286 meters)
Slope: 1 to 3 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, calcareous, mesic Typic Ustifluvents

Typical Pedon

Hickman clay loam, 1 to 3 percent slopes, map unit 23; Sandoval County; Cuba Quadrangle; about 1/2 mile east of La Jara; about 2,100 feet west and 300 feet south of the northeast corner of sec. 33, T. 22 N., R. 1 W. NAD 83, UTM 13—03 24 826 E—39 96 568 N.

A—0 to 4 inches; brown (10YR 5/3) clay loam, dark grayish brown (10YR 4/3) moist; weak medium subangular blocky structure; hard, firm, sticky and plastic; many very fine and fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.

C1—4 to 12 inches; pale brown (10YR 6/3) sandy clay loam, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; many very fine and few fine roots; strongly effervescent; slightly alkaline; clear smooth boundary.
C2—12 to 49 inches; pale brown (10YR 6/3) clay loam, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; few fine and few very fine roots; strongly effervescent; slightly alkaline; clear smooth boundary.
C3—49 to 60 inches; brown (10YR 5/3) sandy clay loam, brown (10YR 4/3) moist; massive; hard, firm, slightly sticky and slightly plastic; few fine and few very fine roots; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 2.5Y, 10YR or 7.5YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4

C horizon
Hue: 2.5Y, 10YR or 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6

Ildefonso Series

Map units: 34, 56, 59, 64, 65, 210, 218
Depth class: very deep
Drainage class: well drained
Landform: hills, mesas, and fan terraces
Parent material: fan alluvium and colluvium derived from mixed sources
Elevation: 5,000 to 6,800 feet (1,524 to 2,073 meters)
Slope: 1 to 70 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy-skeletal, mixed, mesic Ustollic Calciorthids

Typical Pedon

Ildefonso cobbly loam, in an area of mapping unit 59, Harvey-Ildefonso-La Fonda association, 3 to 15 percent slopes; Sandoval County; Sandia Park Quadrangle; about 1 mile west along pipeline from Highway 14 and the 0.5 mile north in the San Pedro Land Grant; unsectionized, NAD 83, UTM 13—03 85 342 E—38 99 611 N.

A—0 to 2 inches; brown (7.5YR 5/2) cobbly loam, dark brown (7.5YR 4/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and very fine roots; 10 percent cobbles and 5 percent gravel; slightly effervescent; moderately alkaline; abrupt smooth boundary.
Bw1—2 to 8 inches; brown (7.5YR 5/2) very gravelly loam, dark brown (7.5YR 4/2) moist; weak fine subangular blocky structure; soft, very friable, sticky and plastic; many fine and very fine roots; 10 percent cobbles and 40 percent gravel; violently effervescent; moderately alkaline; clear smooth boundary.

Bw2—8 to 13 inches; pale brown (10YR 6/3) very gravelly loam, dark yellowish brown (10YR 4/4) moist; weak fine subangular blocky structure; soft, friable, sticky and plastic; common very fine and medium roots; 15 percent cobbles and 40 percent gravel; violently effervescent; moderately alkaline; clear wavy boundary.
Bk1—13 to 32 inches; very pale brown (10YR 7/3) very cobbly sandy loam, light brown (7.5YR 6/4) moist; massive; hard, firm, sticky and plastic; few medium roots; 35 percent cobbles and 20 percent gravel; violently effervescent; many filaments and seams of calcium carbonate, and thick coatings of calcium carbonate on coarse fragments; moderately alkaline; clear wavy boundary.
Bk2—32 to 40 inches; very pale brown (10YR 7/3) very cobbly sandy loam, pink (7.5YR 7/4) moist; massive; hard, firm, sticky and plastic; few coarse roots; 35 percent cobbles and 20 percent gravel; violently effervescent; common filaments and seams of calcium carbonate, and thick coatings of calcium carbonate on coarse fragments; moderately alkaline; clear wavy boundary.
C—40 to 60 inches; very pale brown (10YR 7/3) extremely cobbly sand, light brown (7.5YR 6/4) moist; single grain; loose, nonsticky and nonplastic; 60 percent cobbles and 20 percent gravel; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 8 to 25 percent clay

A and Bw horizons
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 2 to 6
Texture: very stony loam, very cobbly loam, cobbly loam, gravelly sandy loam, and very gravelly sandy loam

Bk horizon
Hue: 5YR, 7.5YR, 10YR
Value: 5 to 8 dry, 4 to 7 moist
Chroma: 1 to 4
Texture: very cobbly loam, very cobbly sandy loam, very gravelly sandy loam, very stony loam, and extremely cobbly sand
Note: This horizon is weakly cemented in some pedons.

Jarmillo Series

Map units: 302, 304
Depth class: very deep
Drainage class: well drained
Landform: stream terraces
Parent material: alluvium, colluvium, and lacustrine sediments derived from rhyolite and tuff
Elevation: 8,500 to 8,800 feet (2,591 to 2,682 meters)
Slope: 1 to 20 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Coarse-loamy, mixed Pachic Haploborolls

Typical Pedon

Jarmillo loam, in an area of mapping unit 302, Tranquilar-Jarmillo complex, 1 to 8 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about 6 miles northeast of La Cueva on the south side of the east-west fence in San Antonio Valley, and 450 feet west of the point where the fence intersects the road between San Antonio Valley and Sulphur Springs, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 55 699 E—39 81 078 N.

A1—0 to 4 inches; dark grayish brown (10YR 4/2) loam, very dark brown (10YR 2/2) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine, common very fine, and few medium roots; slightly acid; clear smooth boundary.

A2—4 to 13 inches; dark grayish brown (10YR 4/2) loam, very dark brown (10YR 2/2) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and few medium roots; slightly acid; clear smooth boundary.

AB—13 to 20 inches; grayish brown (10YR 5/2) loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common fine roots; slightly acid; clear wavy boundary.

Bw1—20 to 26 inches; light brownish gray (10YR 6/2) loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine roots; neutral; gradual wavy boundary.

Bw2—26 to 36 inches; matrix of very pale brown (10YR 7/3) loam, brown (10YR 4/3) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; lamellae (12) are 1/32 to 5/32 inch thick, brown (10YR 5/3) dry and dark brown (10YR 4/3) moist; few fine and medium roots; neutral; gradual wavy boundary.

Bw3—36 to 41 inches; matrix of light yellowish brown (10YR 6/4) fine sandy loam, yellowish brown (10YR 5/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; lamellae (5) are 1/16 to 1/4 inch thick, grayish brown (10YR 5/2) dry and dark grayish brown (10YR 4/2) moist; few very fine and medium roots; neutral; abrupt wavy boundary.

2Bw4—41 to 51 inches; white (2.5Y 8/2) clay loam, light yellowish brown (2.5Y 6/4) moist; moderate coarse prismatic structure; hard, firm, slightly sticky and plastic; organic stains on prism faces; neutral; abrupt wavy boundary.

3C—51 to 60 inches; white (2.5Y 8/2) very fine sandy loam, light yellowish brown (2.5Y 6/4) moist; massive; hard, firm, slightly sticky and slightly plastic; lamellae (1) 1/8 inch thick, grayish brown (10YR 5/2) dry and very dark grayish brown (10YR 3/2) moist; neutral; clear wavy boundary.

Range in Characteristics

Particle-size control section: 8 to 18 percent clay

A horizon
- *Hue:* 2.5Y or 10YR
- *Value:* 4 or 5 dry, 2 or 3 moist
- *Chroma:* 2 or 3
- *Texture:* silt loam or loam

B horizon
- *Hue:* 2.5Y or 10YR
- *Value:* 6 to 8 dry, 3 to 6 moist
- *Chroma:* 2 to 4
- *Texture:* fine sandy loam, loam, and clay loam

C horizon
Hue: 2.5Y or 10YR
Value: 6 to 8 dry, 5 to 7 moist
Chroma: 2 to 4
Texture: loam, very fine sandy loam, and sandy loam

Jarola Series

Map unit: 301
Depth class: very deep
Drainage class: poorly drained
Landform: stream terraces and valley floors
Parent material: stream alluvium derived from rhyolite, tuff, and pumice
Elevation: 8,400 to 8,600 feet (2,560 to 2,621 meters)
Slope: 1 to 5 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Fine-loamy, mixed, frigid Typic Argialbolls

Typical Pedon

Jarola silt loam, in an area of mapping unit 301, Vastine-Jarola silt loams, 0 to 5 percent slopes; Sandoval County; Bland Quadrangle; about 100 feet east of main road to headquarters and about 250 feet south of the Jemez River, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 65 529 E—39 67 968 N.

A—0 to 9 inches; grayish brown (10YR 5/2) silt loam, very dark brown (10YR 2/2) moist; weak medium subangular blocky structure; slightly hard, friable, sticky and plastic; many fine and very fine roots; slightly acid; abrupt smooth boundary.
E—9 to 11 inches; light gray (10YR 6/1) silt loam, very dark gray (10YR 3/1) moist; weak thin platy structure; slightly hard, friable, slightly sticky and slightly plastic; common fine and very fine roots; neutral; abrupt smooth boundary.
Bt1—11 to 17 inches; dark gray (10YR 4/1) silty clay loam, very dark gray (10YR 3/1) moist; moderate medium prismatic structure parting to moderate medium subangular blocky; very hard, very firm, very sticky and very plastic; many fine roots; many thick clay and organic coatings on faces of peds; neutral; clear smooth boundary.
Bt2—17 to 21 inches; gray (10YR 5/1) clay loam, dark gray (10YR 4/1) moist; moderate medium subangular blocky structure; very hard, very firm, sticky and plastic; few fine roots; common moderately thick organic and clay coatings on faces of peds; neutral; clear smooth boundary.
2C1—21 to 42 inches; grayish brown (10YR 5/2) gravelly sandy clay loam, dark grayish brown (10YR 4/2) moist; massive; hard, firm, sticky and plastic; few fine roots; 15 percent gravel; neutral; gradual smooth boundary.
2C2—42 to 60 inches; grayish brown (2.5Y 5/2) very gravelly sandy loam, dark grayish brown (2.5Y 4/2) moist; single grain; loose, nonsticky and nonplastic; 40 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 25 to 40 percent clay

A horizon
Value: 4 or 5 dry, 2 or 3 moist
Chroma: 1 or 2

E horizon
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 1 or 2

B horizon
Hue: 10YR or 2.5Y
Chroma: 1 to 3
Texture: silty clay loam or clay loam

C horizon
Hue: 10YR or 2.5Y
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 1 to 4

Jemez Series

Map units: 88, 163
Depth class: moderately deep
Drainage class: well drained
Landform: hills and interfluves of plateaus
Parent material: slope alluvium derived from tuff
Elevation: 7,000 to 8,800 feet (2,134 to 2,682 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Fine-loamy, mixed Mollic Eutroboralfs

Typical Pedon

Jemez loam, in an area of mapping unit 88, Totavi-Jemez-Rock outcrop association, 0 to 15 percent slopes; Sandoval County; Redondo Peak Quadrangle; about 2 miles east of Redondo Campground, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 54 807 E—39 67 297 N.

A1—0 to 6 inches; dark grayish brown (10YR 4/2) loam, very dark grayish brown (10YR 3/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine roots; slightly alkaline; clear smooth boundary.
A2—6 to 13 inches; pale brown (10YR 6/3) loam, brown (10YR 4/3) moist; weak medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; common medium roots; slightly alkaline; clear smooth boundary.
E—13 to 19 inches; light yellowish brown (10YR 6/4) clay loam, dark yellowish brown (10YR 4/4) moist; weak medium subangular blocky structure; hard, friable, sticky and plastic; common medium roots; slightly alkaline; clear smooth boundary.
Bt—19 to 27 inches; pink (7.5YR 7/4) sandy clay loam, brown (7.5YR 5/4) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; few fine and medium roots; common thin discontinuous clay films on faces of peds; slightly alkaline; abrupt wavy boundary.
R—27 inches; tuff.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay
Depth to lithic contact: 20 to 40 inches

A horizon
Hue: 10YR or 7.5YR
Value: 2 to 5 dry, 2 to 4 moist
Chroma: 1 to 4

E horizon (a lower A horizon in some pedons)
Hue: 10YR or 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4

Bt horizon
Hue: 5YR to 10YR
Value: 4 to 7 dry, 4 or 5 moist
Chroma: 2 to 6
Texture: clay loam or sandy clay loam
Note: 10YR colors occur in the upper part of the Bt horizon or as coatings on faces of peds.

Jocity Series

Map units: 417, 418
Depth class: very deep
Drainage class: moderately well drained
Landform: flood plains and alluvial fans
Parent material: stream alluvium derived from mixed sources
Elevation: 5,300 to 5,600 feet (1,615 to 1,707 meters)
Slope: 0 to 2 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Fine-loamy, mixed, calcareous, mesic Typic Torrifluvents

Typical Pedon

Jocity loam, 0 to 2 percent slope, map unit 417; on the Sandia Pueblo, Sandoval County; Bernalillo Quadrangle; 400 feet south and 450 feet east of the center of sec. 24, of T. 12 N., R. 3 E. NAD 83, UTM 13—03 56 572 E—39 02 182 N.

Ap—0 to 10 inches; brown (10YR 4/3) loam, dark yellowish brown (10YR 3/4) moist; massive; hard, friable, sticky, plastic; common very fine roots; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C1—10 to 26 inches; brown (10YR 4/3) silty clay loam, dark yellowish brown (10YR 3/4) moist; massive; very hard, firm, very sticky and plastic; common very fine roots; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C2—26 to 32 inches; yellowish brown (10YR 5/3) loam, dark brown (10YR 3/3) moist; massive; very hard, friable, very sticky and plastic; few very fine roots; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C3—32 to 50 inches; yellowish brown (10YR 5/4) sandy clay loam, dark yellowish brown (10YR 4/4) moist; massive; very hard, friable, sticky and plastic; few very fine roots; violently effervescent; moderately alkaline; gradual smooth boundary.

C4—50 to 56 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 4/3) moist; massive; slightly hard, very friable, nonsticky and nonplastic; few very fine roots; violently effervescent; strongly alkaline; abrupt smooth boundary.
C5—56 to 60 inches; light yellowish brown (10YR 6/4) loamy sand, yellowish brown (10YR 5/4) moist; loose, nonsticky and nonplastic; violently effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 1 to 5, dry or moist
Texture: loam or clay loam

C horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 1 to 6, dry or moist
Texture: stratified, loamy sand, sandy loam, fine sandy loam, loam, silt loam, sandy clay loam, or clay loam

La Fonda Series

Map units: 55, 59
Depth class: very deep
Drainage class: well drained
Landform: fan terraces and fan piedmonts
Parent material: fan alluvium derived from mixed sources
Elevation: 6,000 to 6,800 feet (1,829 to 2,073 meters)
Slope: 1 to 7 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Camborthids

Typical Pedon

La Fonda loam, in an area of mapping unit 59, Harvey-Ildefonso-La Fonda association, 3 to 15 percent slopes; Sandoval County; Sandia Park Quadrangle; about 1.8 miles west along pipeline from Highway 14 and 700 feet north; unsectionized; NAD 83, UTM 13—03 85 343 E—38 99 641 N.

A—0 to 3 inches; brown (7.5YR 5/4) loam, brown (7.5YR 4/4) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and medium roots; common very fine irregular pores; violently effervescent; moderately alkaline; abrupt smooth boundary.
Bw1—3 to 7 inches; brown (7.5YR 5/4) loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, very friable, sticky and plastic; many fine and very fine roots; common very fine irregular pores; violently effervescent; few fine calcium carbonate accumulations; moderately alkaline; clear smooth boundary.

Bw2—7 to 14 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, friable, sticky and plastic; common very fine roots; common very fine irregular pores; violently effervescent; few fine calcium carbonate masses; moderately alkaline; clear smooth boundary.

Bw3—14 to 26 inches; brown (7.5YR 5/4) loam, brown (7.5YR 4/4) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; common very fine roots; common very fine irregular pores; violently effervescent; few fine calcium carbonate masses; moderately alkaline; clear smooth boundary.

Bk1—26 to 42 inches; light brown (7.5YR 6/4) loam, brown (7.5YR 5/4) moist; weak fine subangular blocky structure; hard, friable, slightly sticky and slightly plastic; few very fine roots; common very fine irregular pores; violently effervescent; common fine soft calcium carbonate accumulations; moderately alkaline; clear smooth boundary.

Bk2—42 to 60 inches; light brown (7.5YR 6/4) loam, brown (7.5YR 5/4) moist; weak medium subangular blocky structure; hard, friable, slightly sticky and slightly plastic; few very fine roots; common very fine irregular pores; violently effervescent; common fine soft calcium carbonate masses; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
- *Hue:* 2.5YR to 7.5YR
- *Value:* 4 to 6 dry, 3 or 4 moist
- *Chroma:* 3 or 4

Bw horizon
- *Hue:* 2.5YR to 7.5YR
- *Value:* 4 to 7 dry, 3 to 5 moist
- *Chroma:* 3 to 6

Bk and C horizons
- *Hue:* 5YR or 7.5YR
- *Chroma:* 3 or 4

Laventana Series

Map units: 601, 603
Depth class: deep
Drainage class: well drained
Landform: mountain slopes and pediments
Parent material: colluvium derived from andesite and granite
Elevation: 7,000 to 8,900 feet (2,134 to 2,713 meters)
Slope: 3 to 55 percent
Climatic data:
- *Mean annual precipitation:* 20 to 25 inches (508 to 635 millimeters)
- *Mean annual air temperature:* 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
- *Frost-free period:* 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed, Mollic Eutroboralfs

Typical Pedon

Laventana very cobbly loam in an area of mapping unit 603, Laventana-Mirand very cobbly loams, 15 to 55 percent slopes; Sandoval County; Bear Springs Peak

Quadrangle; about 2 miles northwest of Bear Springs Peak; NAD 83, UTM 13—03 56 588 E—39 51 074 N.

O—0 to 1 inch; forest litter.
A—1 inch to 4 inches; brown (10YR 4/3) very cobbly loam, dark brown (10YR 3/3) moist; moderate very thin platy structure; soft, very friable, nonsticky and nonplastic; many very fine and few fine roots; many very fine tubular pores; 2 percent stones, 35 percent cobbles, and 15 percent gravel; slightly acid; clear smooth boundary.
E—4 to 11 inches; light yellowish gray (10YR 6/2) gravelly silt loam, dark grayish brown (10YR 4/2) moist; weak medium subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; many very fine and a few fine, medium and coarse roots; common very fine and a few fine tubular pores; 5 percent cobbles and 20 percent gravel; slightly acid; clear smooth boundary.
Bt1—11 to 19 inches; brown (10YR 5/3) very cobbly loam, dark brown (10YR 4/3) moist; strong medium subangular blocky structure parting to strong fine angular blocky; hard, firm, sticky and plastic; common very fine roots; many very fine tubular pores; common thin clay films on faces of peds and in pores; 25 percent cobbles and 15 percent gravel; slightly acid; gradual smooth boundary.
Bt2—19 to 30 inches; brown (10YR 5/3) very gravelly loam, dark brown (10YR 4/3) moist; strong very fine and medium angular blocky structure; hard, firm, sticky and plastic; common very fine roots; many very fine tubular pores; common thin clay films on faces of peds and in pores; 10 percent cobbles and 40 percent gravel, slightly acid; gradual smooth boundary.
Bt3—30 to 50 inches; pale brown (10YR 6/3) very gravelly loam, dark brown (10YR 4/3) moist; moderate medium angular blocky structure; hard, firm, slightly sticky and slightly plastic; few very fine roots; common very fine tubular pores; common moderately thick clay films on faces of peds and in pores; 10 percent cobbles and 40 percent gravel; neutral; abrupt wavy boundary.
2R—50 inches; fractured andesite.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay
Depth to bedrock: between 40 and 60 inches

A horizon
Value: 3 to 6 dry, 2 or 3 moist (when mixed to 7 inches the values are 5 or less dry)
Chroma: 2 or 3
Texture: gravelly sandy loam or very cobbly

E horizon
Value: 5 to 7 dry
Chroma: 2 or 3
Texture: very gravelly loam or gravelly silt loam

Bt horizons
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 3 to 6
Texture: very gravelly loam, very cobbly loam, or very gravelly sandy clay loam
Depth to the base of the Bt horizons: 40 inches or more

Lybrook Series

Map unit: 101
Depth class: very deep
Drainage class: well drained
Landform: stream terraces and valley floors
Parent material: stream alluvium derived from mixed sources
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 0 to 2 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

Lybrook clay loam in an area of map unit 101, Blancot-Lybrook association, 0 to 8 percent slopes; Sandoval County; Lybrook SE Quadrangle; about 15 miles south of Lybrook; 2,640 feet north and 2,640 feet east of the southwest corner of sec. 3, T. 21 N., R. 7 W. NAD 83, UTM 13—02 69 155 E—39 95 751 N.

A—0 to 1 inch; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; few very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—1 inch to 5 inches; brown (10YR 5/3) silty clay loam, brown (10YR 4/3) moist; moderate fine granular structure; soft, very friable, slightly sticky and slightly plastic; few very fine and fine roots; moderately alkaline; clear smooth boundary.
C2—5 to 21 inches; brown (10YR 5/3) clay loam, brown (10YR 4/3) moist; massive; very hard, very firm, sticky and plastic; few very fine roots; moderately alkaline; clear gradual boundary.
C3—21 to 30 inches; pale brown (10YR 6/3) silty clay loam, brown (10YR 4/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; few very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C4—30 to 60 inches; brown (10YR 5/3) clay loam, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; few fine roots; strongly effervescent; very strongly alkaline.

Range in Characteristics

Particle-size control section: 35 to 45 percent clay
Salinity: EC of 2 to 4
Sodicity: SAR of 13 to 30

A horizon
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 or 3

C horizon
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 through 4
Texture: clay loam or silty clay loam

Menefee Series

Map units: 17, 105, 129, 220, 324, 396, 422
Depth class: very shallow and shallow
Drainage class: well drained
Landform: hillslopes, mesas, and mountainsides
Parent material: colluvium and residuum derived from shale
Elevation: 5,700 to 7,800 feet (1,737 to 2,377 meters)
Slope: 2 to 45 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy, mixed, calcareous, mesic, shallow Typic Ustorthents

Typical Pedon

Menefee clay loam, in an area of mapping unit 129, Menefee clay loam, 5 to 35 percent slopes; Sandoval County; Regina Quadrangle; about 1.5 miles north and 1.5 miles east of Regina; 50 feet east and 50 feet north of the center of sec. 22, T. 23 N., R. 1 W. NAD 83, UTM 13—03 26 573 E—40 08 671 N.

A—0 to 5 inches; light yellowish brown (2.5Y 6/4) clay loam, olive brown (2.5Y 4/4) moist; weak fine and medium subangular blocky structure; slightly hard, friable, sticky and plastic; common very fine and few fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—5 to 10 inches; light olive brown (2.5Y 5/4) clay loam, olive brown (2.5Y 4/4) moist; massive; hard, firm, sticky and plastic; few fine and medium roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C2—10 to 17 inches; light brownish gray (2.5Y 6/3) clay loam, grayish brown (2.5Y 5/3) moist; massive; hard, firm, sticky and plastic; few very fine and medium roots; strongly effervescent; very strongly alkaline; gradual irregular boundary.
2Cr—17 inches; soft calcareous shale.

Range in Characteristics

Depth to paralithic contact: 8 to 20 inches

A horizon
Hue: 10YR or 2.5Y
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: loam, clay loam, gravelly loam, or gravelly clay loam

C horizons
Hue: 10YR or 2.5Y
Value: 5 to 7, 4 to 6 moist
Chroma: 2 to 5

Mespun Series

Map unit: 180
Depth class: very deep
Drainage class: excessively drained
Landform: dunes
Parent material: eolian sands derived mainly from sandstone
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)

Slope: 5 to 30 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Mixed, mesic Ustic Torripsamments

Typical Pedon

Mespun loamy fine sand, in an area of mapping unit 180, Councelor-Eslendo-Mespun complex, 5 to 30 percent slopes; Sandoval County; Galisteo SE Quadrangle; about 17 miles south of Galisteo; 1,560 feet south and 2,400 feet east of the NW corner of sec. 29, T. 21 N., R. 7 W. NAD 27; UTM 13—02 65 728 E—39 89 688 N.

A—0 to 6 inches; light yellowish brown (10YR 6/4) loamy fine sand, yellowish brown (10YR 5/4) moist; weak fine granular structure; loose, nonsticky and nonplastic; few very fine roots; moderately alkaline; clear smooth boundary.
C—6 to 60 inches; brown (7.5YR 5/4) loamy sand, brown (7.5YR 4/4) moist; single grain, loose, nonsticky and nonplastic; few very fine roots; moderately alkaline.

Range in Characteristics

Particle-size control section: 3 to 8 percent clay

A horizon
Hue: 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6

C horizon
Hue: 7.5YR
Value: 4 to 7 dry, 3 to 6 moist
Chroma: 3 to 8

Mirand Series

Map units: 283, 603, 604
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes and canyons
Parent material: colluvium derived from rhyolite and tuff
Elevation: 6,900 to 9,500 feet (2,103 to 2,896 meters)
Slope: 5 to 55 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Fine, mixed Mollic Eutroboralfs

Typical Pedon

Mirand loam, in an area of mapping unit 283, Mirand-Alanos complex, 5 to 40 percent slopes; Sandoval County; Valle San Antonio Quadrangle; in the upper end of Redondo Canyon, 20 feet south of gate leading from hot well area into Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 58 447 E—39 73 092 N.

O—0 to 2 inches; decomposed organic matter from grasses and needles.

A—2 to 4 inches; very dark grayish brown (10YR 3/2) loam, very dark brown (10YR 2/2) moist; weak fine granular structure; hard, very friable, sticky and plastic; few fine roots; 5 percent gravel; neutral; abrupt smooth boundary.
Bt1—4 to 9 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; common fine roots; common thin clay films on faces of peds; 10 percent gravel; slightly acid; clear smooth boundary.
Bt2—9 to 15 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; very hard, firm, sticky and plastic; common fine and medium roots; many thick clay films on faces of peds; 15 percent gravel; neutral; clear smooth boundary.
Bt3—15 to 24 inches; yellowish red (5YR 5/6) clay loam, yellowish red (5YR 4/6) moist; moderate medium prismatic structure parting to moderate medium subangular blocky; very hard, firm, very sticky and very plastic; few fine roots; many thick clay films on faces of peds; 10 percent gravel; neutral; clear smooth boundary.
Bt4—24 to 45 inches; reddish brown (5YR 5/4) clay, reddish brown (5YR 4/4) moist; moderate medium and coarse prismatic structure parting to moderate medium subangular blocky; extremely hard, firm, very sticky and very plastic; few very fine roots; many thick clay films on faces of peds; 10 percent gravel; slightly acid; abrupt wavy boundary.
2Bt5—45 to 60 inches; pink (7.5YR 7/4) clay loam, light brown (7.5YR 6/4) moist; common fine distinct strong brown (7.5YR 5/6) mottles; massive; very hard, firm, sticky and plastic; few medium roots; common thick clay film line pores; 10 percent gravel; very strongly acid.

Range in Characteristics

Particle-size control section: 35 to 55 percent clay

A horizon
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 1 or 2
Texture: loam or very cobbly loam

Bt horizon
Hue: 5YR to 10YR
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 3 to 6
Texture: clay loam, gravelly clay loam, sandy clay, clay, or cobbly clay

Montecito Series

Map units: 3, 4, 104
Depth class: very deep
Drainage class: well drained
Landform: hills, summits of mesas and plains
Parent material: eolian material and fan alluvium derived from sandstone and shale
Elevation: 6,000 to 7,600 feet (1,829 to 2,316 meters)
Slope: 1 to 30 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine, mixed, mesic Aridic Haplustalfs

Typical Pedon

Montecito loam, in an area of mapping unit 104, Cochiti-Montecito association, 1 to 30 percent slopes; Sandoval County; Canada Quadrangle; 10 miles northwest of Cochiti Pueblo; 2,400 feet north and 300 feet east of the center of sec. 2, T. 16 N., R. 4 E. NAD 83, UTM 13—03 65 540 E—39 46 249 N.

A—0 to 3 inches; brown (10YR 5/3) loam, brown (10YR 4/3) moist; weak fine granular structure; slightly hard, friable, sticky and plastic; common medium roots; neutral; abrupt smooth boundary.

Bt1—3 to 9 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; weak coarse prismatic structure parting to moderate medium subangular blocky; hard, firm, very sticky and very plastic; few fine and very fine roots; many thick clay films on faces of peds; neutral; clear smooth boundary.

Bt2—9 to 15 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; weak coarse prismatic structure parting to moderate medium subangular blocky; hard, firm, very sticky and very plastic; few very fine roots; many thick clay films on faces of peds; slightly alkaline; clear smooth boundary.

Bt3—15 to 22 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; few very fine roots; many thick clay films on faces of peds; moderately alkaline; abrupt wavy boundary.

2Bk1—22 to 37 inches; pinkish white (7.5YR 8/2) sandy loam, pink (7.5YR 7/4) moist; massive; soft, friable, slightly sticky and slightly plastic; few very fine roots; 10 percent gravel; violently effervescent; common weakly cemented calcium carbonate masses; moderately alkaline; gradual wavy boundary.

2Bk2—37 to 60 inches; pinkish white (7.5YR 8/2) gravelly sandy loam, pink (7.5YR 7/4) moist; massive; soft, friable, slightly sticky and slightly plastic; 25 percent gravel; violently effervescent; common weakly cemented calcium carbonate masses; moderately alkaline.

Range in Characteristics

Particle-size control section: 35 to 50 percent clay
Depth to the calcic horizon: 10 to 35 inches

A Horizon
- *Hue:* 7.5YR or 10YR
- *Value:* 4 to 6 dry, 3 to 5 moist
- *Chroma:* 3 to 6
- *Texture:* fine sandy loam, loam, or extremely bouldery loam

Bt Horizon
- *Hue:* 7.5YR or 10YR
- *Value:* 4 to 6 dry, 3 to 5 moist.
- *Chroma:* 3 to 6

Bk Horizon
- *Hue:* 7.5YR or 10YR
- *Value:* 6 to 8 dry, 5 to 8 moist
- *Chroma:* 1 to 4
- *Texture:* sandy loam, gravelly sandy loam, loam, or clay loam

Nyjack Series

Map unit: 162
Depth class: moderately deep
Drainage class: well drained
Landform: summits of mesas and plateaus
Parent material: eolian material and slope alluvium derived from tuff
Elevation: 6,000 to 7,000 feet (1,829 to 2,134 meters)
Slope: 1 to 5 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, mesic Aridic Haplustalfs

Typical Pedon

Nyjack loam, in an area of mapping unit 162, Hackroy-Nyjack association, 1 to 5 percent slopes; Los Alamos County; Frijoles Quadrangle; about .5 mile east of LASL Administration Building, 2,000 feet west, 660 feet west, 660 feet south of the southwest corner of sec. 21, T. 19 N., R. 6 E. NAD 83, UTM 13—03 81 468 E—39 68 841 N.

A—0 to 3 inches; brown (10YR 5/3) loam, dark brown (7.5YR 3/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine roots; many vesicular pores; slightly acid; abrupt smooth boundary.
Bt1—3 to 13 inches; brown (7.5YR 5/4) clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, very friable, slightly sticky and slightly plastic; many fine medium roots; many vesicular pores; few thin clay films on faces of peds; neutral; clear smooth boundary.
Bt2—13 to 24 inches; brown (7.5YR 4/4) clay loam, dark brown (7.5YR 3/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; few fine roots; many fine tubular pores; thin discontinuous clay films on faces of peds; neutral; abrupt smooth boundary.
2C—24 to 39 inches; light brown (7.5YR 6/4) gravelly sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few fine roots; 25 percent pumice gravel; neutral; abrupt smooth boundary.
Cr—39 inches; tuff bedrock.

Range in Characteristics

Particle-size control section: 27 to 35 percent clay
Depth to paralithic contact: 20 to 40 inches

A horizon
Hue: 7.5YR or 10YR
Value: 4 or 5 dry, 3 or 4 moist
Chroma: 2 to 4, dry or moist

Bt horizons
Hue: 5YR to 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 3 to 6, dry or moist

Bt3 horizon (when present)
Hue: 5YR to 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 3 to 6, dry or moist

2C horizon
Hue: 5YR to 10YR
Value: 4 to 6 dry, 4 or 5 moist
Chroma: 3 or 4 dry

Orejas Series

Map units: 3, 100, 504
Depth class: shallow
Drainage class: well drained
Landform: mesas and plateaus
Parent material: eolian material, slope alluvium, and colluvium derived from basalt
Elevation: 6,000 to 7,600 feet (1,829 to 2,316 meters)
Slope: 1 to 40 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Clayey-skeletal, mixed, mesic Lithic Haplustalfs

Typical Pedon

Orejas cobbly loam, in an area of mapping unit 3, Montecito-Orejas complex, 1 to 7 percent slopes; Sandoval County; Cabezon Peak Quadrangle; on Mesa Prieta; 2,000 feet north and 350 feet east of the southwest corner of sec. 10, T. 15 N., R. 2 W. NAD 83, UTM 13—03 14 762 E—39 34 960 N.

A—0 to 2 inches; yellowish brown (10YR 5/4) cobbly loam, dark yellowish brown (10YR 3/4) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; 30 percent cobbles; slightly alkaline; abrupt smooth boundary.
Bt1—2 to 5 inches; brown (10YR 4/3) very cobbly clay loam, dark brown(10YR 3/3) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; common moderately thick clay films on faces of peds; 45 percent cobbles; neutral; clear smooth boundary.
Bt2—5 to 14 inches; dark yellowish brown (10YR 4/4) very cobbly clay loam, dark yellowish brown (10YR 3/4); moderate fine and medium subangular blocky structure; hard, firm, very sticky and very plastic; many thick clay films on faces of peds; 45 percent cobbles; moderately alkaline; clear smooth boundary.
Bt3—14 to 17 inches; brown (10YR 5/3) very cobbly clay loam, brown (10YR 4/3) moist; moderate medium and coarse subangular blocky structure; hard, firm, sticky and plastic; few moderately thick clay films on faces of peds; 45 percent cobbles; slightly effervescent; moderately alkaline; clear smooth boundary.
C—17 to 19 inches; pale brown (10YR 6/3) very gravelly clay loam, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; 10 percent cobbles and 30 percent gravel; violently effervescent; moderately alkaline; abrupt smooth boundary.
R—19 inches; basalt.

Range in Characteristics

Particle-size control section: 35 to 50 percent clay
Depth to bedrock: 10 to 20 inches

A horizon
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 3 or 4 moist
Chroma: 2 to 4
Texture: cobbly loam, very cobbly loamy, or very stony loam

Bt horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 2 to 4

C horizons
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 or 3
Texture: very gravelly clay loam or very cobbly clay loam

Origo Series

Map units: 74, 75
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: slope alluvium and colluvium derived from rhyolite and tuff
Elevation: 8,600 to 10,000 feet (2,621 to 3,048 meters)
Slope: 15 to 65 percent
Climatic data:
Mean annual precipitation: 25 to 30 inches (635 to 762 millimeters)
Mean annual air temperature: 38 to 42 degrees F. (3.3 to 5.6 degrees C.)
Frost-free period: 45 to 60 days

Taxonomic class: Loamy-skeletal, mixed Psammentic Cryoboralfs

Typical Pedon

Origo very cobbly sandy loam, in an area of mapping unit 75, Origo very cobbly sandy loam, 35 to 65 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about 7 miles north of La Cueva on the north side of Cerro Seco, Baca Location No. 1; NAD 83, UTM 13—03 58 587 E—39 80 079 N.

0—0 to 1 inch; leaves, needles, twigs, and bark.
A1—1 inch to 5 inches; gray (10YR 5/1) very cobbly sandy loam, very dark gray (10YR 3/1) moist; moderate fine and medium granular structure; soft, very friable, slightly sticky and slightly plastic; few coarse and many fine roots; 10 percent stones, 40 percent cobbles, and 5 percent gravel; slightly acid; clear smooth boundary.
A2—5 to 11 inches; light brownish gray (10YR 6/2) very cobbly sandy loam, dark grayish brown (10YR 4/2) moist; moderate fine and medium granular structure; soft, very friable, slightly sticky and slightly plastic; many fine, medium roots and common coarse roots; 10 percent stones, 40 percent cobbles, and 5 percent gravel; neutral; gradual smooth boundary.
E—11 to 31 inches; very pale brown (10YR 7/3) very cobbly sandy loam, brown (10YR 5/3) moist; weak fine subangular blocky structure parting to moderate fine granular; slightly hard, friable, slightly sticky and nonplastic; many fine and common medium roots; 10 percent stones, 40 percent cobbles, and 5 percent gravel; neutral; gradual wavy boundary.
Bt1—31 to 55 inches; very pale brown (10YR 7/3) very cobbly sandy loam, brown (10YR 5/3) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and nonplastic; (lamellae are 1/4 to 1 inch thick and comprise about 7 inches of the horizon; light brown (7.5YR 6/4) sandy loam, brown (7.5YR 5/4) moist;) massive; slightly hard, friable, slightly sticky and slightly plastic; few coarse medium roots;) clay films on sand grains and clay bridging sand grains in

lamellae; 10 percent stones and 40 percent cobbles; very strongly acid; gradual wavy boundary.

Bt2—55 to 60 inches; white (10YR 8/2) very cobbly loamy sand, very pale brown (10YR 7/3) moist; massive; slightly hard, firm, nonsticky and nonplastic; (lamellae are 1/4 to 1 inch thick; light brown (7.5YR 6/4) sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; clay films on sand grains and clay bridging sand grains;) few coarse and medium roots; 10 percent stones and 40 percent cobbles; very strongly acid.

Range in Characteristics

Particle-size control section: 5 to 20 percent clay

A horizon
Value: 5 or 6 dry, 3 to 5 moist
Chroma: 1 to 3

E horizon
Hue: 7.5YR or 10YR
Value: 7 or 8 dry, 5 to 7 moist
Chroma: 1 to 4
Texture: extremely cobbly sandy loam and very cobbly sandy loam

Bt horizon
Hue: 10YR or 7.5YR
Value: 5 to 8 dry, 5 to 7 moist
Chroma: 2 to 4
Texture: very cobbly loamy sand, very cobbly sandy loam, and extremely cobbly sandy loam
Depth to the Bt horizon: 18 to 34 inches

Bt lamellae
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: sandy loam and sandy clay loam

Orlie Series

Map units: 24, 26, 422
Depth class: very deep
Drainage class: well drained
Landform: dipslopes of cuestas, mesas, hills, and valley sides
Parent material: eolian material and fan alluvium derived from sandstone and shale
Elevation: 6,100 to 7,500 feet (1,859 to 2,286 meters)
Slope: 0 to 8 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, mesic Aridic Haplustalfs

Typical Pedon

Orlie loam, in an area of mapping unit 26, Orlie loam, 0 to 8 percent slopes; Sandoval County; Jarosa Quadrangle; 6 miles west of the continental divide along the boundary

of the Jicarilla Indian Reservation; 1,075 feet south and 700 feet west of the northeast corner of sec. 6, T. 21 N., R. 3 E. NAD 83, UTM 13—03 51 252 E—39 94 408 N.

A—0 to 2 inches; pale brown (10YR 6/3) loam, dark brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; few coarse and common fine roots; moderately alkaline; clear smooth boundary.
Bt1—2 to 13 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common fine and very fine roots; few thin clay films on faces of peds; moderately alkaline; clear smooth boundary.
Bt2—13 to 22 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; weak medium subangular blocky structure; hard, firm, sticky and plastic; few fine and medium roots; few thin clay films on faces of peds; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—22 to 36 inches; pale brown (10YR 6/3) silty clay loam, brown (10YR 5/3) moist; massive; hard, firm, sticky and plastic; few very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C2—36 to 50 inches; brown (7.5YR 5/4) clay loam, brown (10YR 5/3) moist; massive; hard, firm, sticky and plastic; few very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C3—50 to 60 inches; pale brown (10YR 6/3) silty clay loam, dark brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; few fine roots; slightly effervescent; moderate alkaline.

Range in Characteristics

Particle-size control section: 27 to 35 percent clay

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: fine sandy loam or loam

Bt horizon
Hue: 5YR, 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: clay loam or silty clay loam

C or Bk horizons (when present)
Hue: 7.5YR or 10YR
Value: 4 or 6 dry, 3 or 5 moist
Chroma: 3 or 4 dry, 3 to 6 moist
Texture: sandy clay loam, clay loam, or silty clay loam

Osha Series

Map units: 500, 608
Depth class: deep
Drainage class: somewhat excessively drained
Landform: mountain slopes and ridges
Parent material: colluvium and residuum derived from granite
Elevation: 7,000 to 9,000 feet (2,134 to 2,743 meters)
Slope: 3 to 70 percent

Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed Typic Haploborolls

Typical Pedon

Osha gravelly coarse sandy loam, in an area of mapping unit 608, Osha association, 3 to 55 percent slopes; Sandoval County; San Miquel Mountain Quadrangle; about 6 miles east and 2 miles south of Laventana; NAD 83, UTM 13—03 31 585 E—39 62 960 N.

A—0 to 3 inches; very dark gray (10YR 3/1) gravelly coarse sandy loam, (10YR 2/1) moist; moderate very fine granular structure; soft, very friable, nonsticky and nonplastic; many very fine, fine, and medium roots; common very fine tubular pores; 20 percent gravel; neutral; clear smooth boundary.
AB—3 to 8 inches; grayish brown (10YR 5/2) gravelly coarse sandy loam, very dark grayish brown (10YR 3/2) moist; moderate medium and fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; common very fine and medium and few coarse roots; many very fine tubular pores; 20 percent gravel; slightly acid; clear smooth boundary.
Bw—8 to 16 inches; light brown (7.5YR 6/4) gravelly coarse sandy loam, dark yellowish brown (10YR 3/4) moist; moderate medium and fine subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; common very fine and common medium roots; many very fine tubular pores; 20 percent gravel; neutral; clear smooth boundary.
Ct1—16 to 32 inches; strong brown (7.5YR 5/6) extremely gravelly coarse sandy loam, strong brown (7.5YR 4/6) moist; massive; weathered granite has retained the original shape and relative position of the altered minerals; fractures between mineral grains that are less than 1 inch apart; hard, firm, nonsticky and nonplastic; many very fine roots; common moderately thick clay films on mineral grains; 75 percent gravel; neutral; diffuse wavy boundary.
Ct2—32 to 60 inches; reddish yellow (7.5YR 6/6) extremely gravelly loamy coarse sand, strong brown (7.5YR 5/6) moist; massive; consolidated rock structure; weathered granite has retained the original shape and relative position of the altered minerals; fractures between mineral grains are 0.5 to 2.5 inches apart; hard, friable, nonsticky and nonplastic; common very fine roots; few moderately thick clay films on mineral grains; 80 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 6 to 12 percent clay
Depth to granite (lithic) contact: 40 to 60 inches, and deeper in some pedons

A horizon
Hue: 7.5YR or 10YR
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 1 to 3
Texture: gravelly coarse sandy loam and very gravelly coarse sandy loam

B or C horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: gravelly coarse sandy loam, very gravelly coarse sandy loam, extremely gravelly coarse sandy loam, or extremely gravelly loamy coarse sand

Palon Series

Map units: 71, 72
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: slope alluvium and colluvium derived mainly of rhyolite
Elevation: 8,500 to 9,500 feet (2,591 to 2,896 meters)
Slope: 15 to 65 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Loamy-skeletal, mixed Psammentic Eutroboralfs

Typical Pedon

Palon very cobbly sandy loam; 35 to 65 percent slopes, map unit 72; Sandoval County; Valle San Antonio Quadrangle; about 5 miles north of La Cueva on the south side of Cerro Seco, Baca Location No. 1; NAD 83, UTM 13—03 58 417 E—39 78 037 N.

Oi—0 to 2 inches; leaves, needles, twigs, and bark.
A1—2 to 4 inches; dark gray (10YR 4/3) very cobbly sandy loam, very dark gray (10YR 3/1) moist; moderate fine and medium granular structure; soft, very friable, slightly sticky and nonplastic; many fine and very fine roots and common medium roots; 10 percent stones, 30 percent cobbles, and 5 percent gravel; neutral; abrupt smooth boundary.
A2—4 to 10 inches; light brownish gray (10YR 6/2) extremely cobbly sandy loam, dark grayish brown (10YR 4/2) moist; moderate fine and medium granular structure; soft, very friable, slightly sticky and nonplastic; many fine and very fine roots and common medium roots; 20 percent stones, 40 percent cobbles, and 10 percent gravel; neutral; clear wavy boundary.
E—10 to 32 inches; light gray (10YR 7/2) extremely cobbly sandy loam, brown (10YR 5/3) moist; weak fine granular structure; soft, very friable, slightly sticky and nonplastic; many medium, common fine, and few coarse roots; 20 percent stones, 45 percent cobbles, and 5 percent gravel; neutral; abrupt wavy boundary.
Bt1—32 to 53 inches; pink (7.5YR 7/4) very cobbly sandy loam, brown (7.5YR 5/4) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; (lamellae are 1/4 to 1 inch thick; total thickness of lamellae is 6 inches or more; light brown (7.5YR 6/4) sandy loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; clay bridging sand grains;) few fine and medium roots; 15 percent stones, 35 percent cobbles, and 5 percent gravel; neutral; gradual wavy boundary.
Bt2—53 to 60 inches; pink (7.5YR 7/4) very cobbly sandy loam, brown (7.5YR 5/4) moist; weak medium subangular blocky structure; soft, very friable, slightly sticky and nonplastic; (lamellae are 1/4 to 1 inch thick; total thickness is 6 inches or more; light brown (7.5YR 6/4) sandy clay loam, brown (7.5YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; clay bridging sand grains;) few fine roots; 10 percent stones, 30 percent cobbles, and 5 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 10 to 25 percent clay

A horizon
Value: 4 to 6 dry, 2 to 4 moist
Chroma: 1 to 3
Texture: cobbly sandy loam, very cobbly sandy loam, or extremely cobbly sandy loam

E horizon
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 4 to 7 moist
Chroma: 2 to 6
Texture: very cobbly sandy loam or extremely cobbly sandy loam

Bt horizon
Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 6
Texture: very cobbly sandy loam or extremely cobbly sandy loam

Pastura Series

Map unit: 262
Depth class: very shallow to shallow
Drainage class: well drained
Landform: sideslopes of hills and mesas
Parent material: residuum derived from limestone
Elevation: 5,400 to 5,800 feet (1,646 to 1,768 meters)
Slope: 1 to 4 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 140 to 150 days

Taxonomic class: Loamy, mixed, mesic, shallow Ustollic Paleorthids

Typical Pedon

Pastura loam, in an area of mapping unit 262, Pastura loam, 1 to 4 percent slopes; Sandoval County; San Felipe Mesa Quadrangle; about 4 miles northwest of Placitas and 100 feet east and 2,640 feet south of the northwest corner of sec. 20, T. 13 N., R. 1 W. NAD 83, UTM 13—03 20 663 E—39 12 515 N.

A—0 to 3 inches; light yellowish brown (10YR 6/4) loam, brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots; moderately alkaline; abrupt smooth boundary.
Bw—3 to 10 inches; light yellowish brown (10YR 6/4) gravelly loam, dark yellowish brown (10YR 4/4) moist; weak medium subangular blocky structure; slightly hard, friable, sticky and plastic; common fine and very fine roots; 15 percent gravel; moderately alkaline; clear smooth boundary.
Bk—10 to 14 inches; very pale brown (10YR 7/4) gravelly loam, yellowish brown (10YR 5/4) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; few fine and very fine roots; 15 percent gravel; moderately alkaline; abrupt wavy boundary.
Bkm—14 inches; indurated petrocalcic broken into plates 3 to 12 inches horizontally and 2 to 4 inches vertically.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Depth to petrocalcic horizon: 5 to 20 inches

A horizon
Hue: 5YR to 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 6

Bw horizon (or Bk horizon where present)
Hue: 5YR to 10YR
Value: 4 to 7 dry, 4 to 6 moist
Chroma: 2 to 6

Note: A Bkm horizon, which consists of a series of strongly cemented to indurated petrocalcic horizons, may be present beneath the uppermost-indurated horizon. These layers range in thickness from 6 to 36 inches separated by gravelly and cobbly soil material.

Pavo Series

Map unit: 74
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: colluvium derived mainly from tuff and pumice
Elevation: 8,600 to 10,000 feet (2,621 to 3,048 meters)
Slope: 5 to 20 percent
Climatic data:
Mean annual precipitation: 25 to 30 inches (635 to 762 millimeters)
Mean annual air temperature: 38 to 42 degrees F. (3.3 to 5.6 degrees C.)
Frost-free period: 45 to 60 days

Taxonomic class: Fine-loamy, mixed Cryic Paleborolls

Typical Pedon

Pavo loam, in an area of mapping unit 74, Origo-Pavo association, 5 to 35 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about 1 mile south of hot springs in the San Antonio Valley, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 58 992 E—39 80 935 N.

A1—0 to 9 inches; grayish brown (10YR 5/2) loam, very dark grayish brown (10YR 3/2) moist; weak medium granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots; slightly acid; clear wavy boundary.

A2—9 to 12 inches; grayish brown (10YR 5/2) sandy loam, very dark grayish brown (10YR 3/2) moist; weak coarse subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; many very fine roots; 5 percent cobbles and 5 percent gravel; neutral; clear wavy boundary.

E—12 to 25 inches; very pale brown (10YR 7/3) sandy loam, brown (10YR 5/3) moist; weak fine subangular blocky structure; soft, very friable, nonsticky and nonplastic; few fine roots; 10 percent gravel; neutral; clear wavy boundary.

E/Bt1—25 to 35 inches; very pale brown (10YR 7/3) sandy loam, brown (10YR 5/3) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and nonplastic; (lamellae are .4 to .7 inch thick and total 1.5 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; slightly hard, friable, slightly

sticky and slightly plastic; clay films on sand grains and clay bridges between grains in lamellae;) 5 percent gravel; neutral; clear wavy boundary.

E/Bt2—35 to 45 inches; very pale brown (10YR 7/3) fine sandy loam, brown (10YR 5/3) moist; weak fine subangular blocky structure; soft, very friable, slightly sticky and nonplastic; (lamellae are about .5 inch thick and total about 5 inches yellowish brown (10YR 5/4) sandy clay loam, brown (10YR 4/3) moist; hard, friable, slightly sticky and slightly plastic; clay films on sand grains and clay bridges between grains in lamellae;) 5 percent gravel; neutral; clear smooth boundary.

2Bt1—45 to 50 inches; brown (7.5YR 5/4) gravelly clay loam, dark brown (7.5YR 4/4) moist; weak fine subangular blocky structure; hard, friable, sticky and plastic; thick continuous clay films on coarse fragments; 30 percent gravel; slightly acid; clear smooth boundary.

3Bt2—50 to 60 inches; very pale brown (10YR 7/4) sandy loam, dark yellowish brown (10YR 4/4) moist; weak coarse subangular blocky structure; hard, friable, slightly sticky and slightly plastic; clay films on sand grains and clay bridges between grains; 9 percent cobbles and 5 percent gravel; neutral.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Argillic horizon: greater than 24 inches deep and composed mainly of lamellae thicker than 1 cm

A horizon
Value: 4 or 5 dry, 2 or 3 moist
Chroma: 2 or 3
Texture: loam or sandy loam

E horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: sandy loam or fine sandy loam

Bt horizon
Hue: 5YR to 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: sandy loam, fine sandy loam, or sandy clay loam

2 and 3Bt horizons
Hue: 5YR to 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: gravelly clay loam or sandy loam

Penistaja Series

Map units: 68, 207, 240
Depth class: very deep
Drainage class: well drained
Landform: alluvial fans, bajadas, cuestas, hills, mesas, and plateaus
Parent material: eolian material and fan alluvium derived from sandstone and shale
Elevation: 5,400 to 6,400 feet (1,646 to 1,951 meters)
Slope: 1 to 7 percent

Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Haplargids

Typical Pedon

Penistaja loamy fine sand, in an area of mapping unit 68, Penistaja-Querencia complex, 2 to 7 percent slopes; Sandoval County; about 4 miles east of Marquez; 700 feet north and 2,100 feet west of the southeast corner of sec. 24, T. 12 N., R. 2 W.

A—0 to 2 inches; light yellowish brown (10YR 6/4) loamy fine sand, yellowish brown (10YR 5/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few very fine roots; slightly alkaline; abrupt smooth boundary.
Bt—2 to 15 inches; strong brown (7.5YR 5/6) sandy clay loam, strong brown (7.5YR 4/6) moist; moderate fine and medium subangular blocky structure; slightly hard, friable, sticky and plastic; few very fine and fine roots; common moderately thick clay films on faces of peds; slightly alkaline; clear smooth boundary.
Btk—15 to 27 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; few very fine and fine roots; few thin clay films on faces of peds; slightly effervescent; slightly alkaline; clear smooth boundary.
Bk—27 to 38 inches; pale brown (10YR 6/3) clay loam, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; few fine roots; slightly effervescent; few fine calcium carbonate accumulations; moderately alkaline; gradual smooth boundary.
C—38 to 60 inches; light yellowish brown (10YR 6/4) sandy clay loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, sticky and plastic; slightly effervescent; slightly alkaline.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay

A horizon
Hue: 5YR to 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 6
Texture: loamy fine sand, fine sandy loam, and very fine sandy loam

Bt horizon
Hue: 5YR or 7.5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: sandy clay loam or clay loam

Bk and C horizons
Hue: 5YR to 10YR
Value: 4 to 8 dry, 3 to 7 moist
Chroma: 3 to 6
Texture: loam, fine sandy loam, loam, or sandy clay loam

Peralta Series

Map units: 433, 434, 437, 835, 842
Depth class: very deep
Drainage class: somewhat poorly drained

Landform: flood plains
Parent material: stream alluvium derived from mixed sources
Elevation: 5,000 to 5,500 feet (1,524 to 1,676 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Coarse-loamy, mixed, calcareous, mesic Typic Ustifluvents

Typical Pedon

Peralta loam, in an area of mapping unit 434, Peralta loam, 1 to 3 percent slopes; Sandoval County; Bernalillo Quadrangle; about 1.5 miles northwest of the Sandia Pueblo; 300 feet south and 1,980 feet east of the northwest corner of sec. 13, T. 12 N., R. 3 E. NAD 83, UTM 13—03 56 360 E—39 04 486 N.

Ap—0 to 10 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; massive; hard, firm, sticky and slightly plastic; many fine and very fine roots; strongly effervescent; slightly alkaline; abrupt smooth boundary.
C1—10 to 16 inches; brown (7.5YR 5/4) very fine sandy loam, dark brown (7.5YR 3/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; common fine roots; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C2—16 to 20 inches; brown (7.5YR 4/4) clay loam, dark brown (7.5YR 3/4) moist; few fine faint brown (10YR 5/3) and few fine distinct brown (7.5YR 4/6) mottles; massive; very hard, firm, sticky and plastic; very fine roots; violently effervescent; moderately alkaline, abrupt smooth boundary.
C3—20 to 28 inches; light yellowish brown (10YR 6/4) fine sandy loam, dark yellowish brown (10YR 4/4) moist; few fine and prominent strong brown (7.5YR 5/6) mottles; massive; soft, very friable, nonsticky and nonplastic; few very fine roots; strongly effervescent, moderately alkaline; clear smooth boundary.
C4—28 to 40 inches; pale brown (10YR 6/3) loamy sand, dark yellowish brown (10YR 4/4) moist; massive; loose, nonsticky and nonplastic; few very fine roots; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C5—40 to 45 inches; brown (7.5YR 5/2) silt loam, dark brown (7.5YR 3/2) moist; common fine distinct yellowish red (5YR 4/6) mottles; massive; hard, firm, sticky and slightly plastic; violently effervescent; moderately alkaline; abrupt smooth boundary.
C6—45 to 60 inches; yellowish brown (10YR 5/4) loamy fine sand, dark yellowish brown (10YR 3/4) moist; single grain; loose, nonsticky and nonplastic; strongly effervescent; slightly alkaline.

Range in Characteristics

Particle-size control section: less than 18 percent clay
Depth to redoximorphic features: 12 to 30 inches

A horizon
Value: 5 or 6 dry, 3 to 5 moist
Chroma: 3 or 4
Texture: loam or clay loam

C horizon
Hue: 7.5YR or 10YR
Value: 3 to 7 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: stratified silt loam, clay loam, very fine sandy loam, coarse sand, loam, sandy clay loam, fine sandy loam, sandy loam, loamy fine sand, and loamy sand
Salinity: EC of 4 to 16

Pinavetes Series

Map units: 120, 130, 213, 250, 420
Depth class: very deep
Drainage class: excessively drained
Landform: dunes and valley sides
Parent material: eolian sands derived from sandstone
Elevation: 5,200 to 6,100 feet (1,585 to 1,859 meters)
Slope: 0 to 35 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Mixed, mesic Ustic Torripsamments

Typical Pedon

Pinavetes loamy sand, in an area of mapping unit 120, Pinavetes loamy sand, 3 to 5 percent slopes; Sandoval County; Bernalillo NM Quadrangle; about 5 miles southeast of Zia Pueblo; 1,100 feet south and 1,525 feet east of the northwest corner of section 24, T. 14 N., R. 2 E. NAD 83, UTM 13—03 47 076 E—39 22 110 N.

A—0 to 10 inches; light yellowish brown (10YR 6/4) loamy sand, yellowish brown (10YR 5/4) moist; single grain; loose, nonsticky and nonplastic; many very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—10 to 35 inches; light yellowish brown (10YR 6/4) sand, yellowish brown (10YR 5/4) moist; single grain; loose, nonsticky and nonplastic; few very fine roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C2—35 to 60 inches; light yellowish brown (10YR 6/4) sand, yellowish brown (10YR 5/4) moist; single grain; loose, nonsticky and nonplastic; few very fine roots; 10 percent gravel; strongly effervescent; moderately alkaline.

Range in Characteristics

A horizon
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 or 4
Texture: sand, loamy sand, or loamy fine sand

C horizon
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 to 6
Texture: sand, fine sand, or loamy sand

Pinitos Series

Map unit: 206
Depth class: very deep
Drainage class: well drained
Landform: dipslopes of cuestas, hills, mesas, and fan terraces
Parent material: fan alluvium derived from sandstone and shale
Elevation: 7,000 to 7,600 feet (2,134 to 2,316 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 49 to 51 degrees F. (9.5 to 10.5 degrees C.)
Frost-free period: 100 to 120 days

Taxonomic class: Fine-loamy, mixed, mesic Aridic Haplustalfs

Typical Pedon

Pinitos loam, in an area of mapping unit 206, Pinitos loam, 1 to 15 percent slopes; Sandoval County; Regina Quadrangle; 1,500 feet south and 1,300 feet east of the northwest corner of sec. 33, T. 23 N., R. 1 W. NAD 83, UTM 13—03 24 475 E—40 05 845 N.

A—0 to 4 inches; yellowish brown (10YR 5/4) loam, dark brown (10YR 4/3) moist; weak medium subangular blocky structure; slightly hard, friable, sticky and plastic; many very fine and common fine roots; many very fine and fine pores; neutral; clear smooth boundary.

Bt1—4 to 10 inches; brown (7.5YR 4/4) clay loam, dark brown (10YR 3/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common very fine and fine roots; few medium pores; many thick clay films on faces of peds; neutral; clear smooth boundary.

Bt2—10 to 27 inches; strong brown (7.5YR 5/6) clay loam, dark brown (7.5YR 4/4) moist; moderate medium and coarse subangular blocky structure; hard, firm, sticky and plastic; few very fine and fine roots; common and medium moderately thick clay films on faces of peds; neutral; clear smooth boundary.

Btk—27 to 39 inches; strong brown (7.5YR 5/6) clay loam, dark brown (7.5YR 4/4) moist; moderate coarse subangular blocky structure; hard, firm, sticky and plastic; few fine and medium roots; many very fine and fine pores; few fine clay films on faces of peds; slightly effervescent; few fine accumulations of calcium carbonate; slightly alkaline; gradual smooth boundary.

C—39 to 60 inches; strong brown (7.5YR 5/6) clay loam, dark brown (7.5YR 4/4) moist; massive; hard, firm, sticky and plastic; few fine and medium roots; slightly effervescent; slightly alkaline.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay

A Horizon
Hue: 7.5YR or 10YR
Value: 5 or 6 dry, 3 or 4 moist
Chroma: 3 or 4 moist

Bt Horizon
Hue: 7.5YR or 10YR
Value: 4 or 5 dry, 3 or 4 moist
Chroma: 4 to 6 dry

Bk or C Horizons
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 4 to 6

Placitas Series

Map unit: 63
Depth class: moderately deep
Drainage class: well drained
Landform: fan terraces
Parent material: fan alluvium from conglomerate
Elevation: 5,700 to 6,300 feet (1,737 to 1,920 meters)
Slope: 8 to 40 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy-skeletal, mixed, mesic Ustollic Calciorthids

Typical Pedon

Placitas gravelly loam, in an area of mapping unit 63, Placitas gravelly loam, 8 to 40 percent slopes; Sandoval County; Placitas Quadrangle; about 2 miles northeast of Placitas; 400 feet north and 200 feet west of the southeast corner of sec. 21, T. 13 N., R. 5 E. NAD 83, UTM 13—03 71 988 E—39 10 875N.

A—0 to 5 inches; pale brown (10YR 6/3) gravelly loam, brown (10YR 4/3) moist; weak fine and medium granular structure; soft, very friable, slightly sticky and slightly plastic; many fine and few very fine roots; 30 percent gravel; strongly effervescent; moderately alkaline; clear smooth boundary.
Bw—5 to 10 inches; very pale brown (10YR 7/4) very gravelly sandy loam, yellowish brown (10YR 5/4) moist; weak fine subangular blocky structure; soft, very friable, slightly sticky and slightly plastic; few fine and very fine roots; 40 percent gravel; violently effervescent; moderately alkaline; clear smooth boundary.
Bk—10 to 27 inches; very pale brown (10YR 7/3) very gravelly sandy loam, brown (10YR 5/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; few fine and very fine roots; 55 percent gravel; violently effervescent; many seams and filaments of calcium carbonate; moderately alkaline; clear smooth boundary.
R—27 inches; conglomerate.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay
Depth to lithic contact: 20 to 40 inches

A horizon
Hue: 10YR to 5YR
Value: 4 or 5 moist
Chroma: 2 to 4

B horizon
Hue: 7.5YR or 10YR
Value: 6 or 7 dry, 4 or 5 moist
Chroma: 3 or 4

Poley Series

Map units: 67
Depth class: very deep
Drainage class: well drained
Landform: sideslopes of fan terraces
Parent material: colluvium derived from shale and sandstone
Elevation: 6,000 to 7,000 feet (1,829 to 2,134 meters)
Slope: 3 to 30 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine, mixed, mesic Ustollic Haplargids

Typical Pedon

Poley very cobbly loam in an area of mapping unit 67, Sandoval-Poley complex, 3 to 30 percent slopes; Sandoval County; Cerro Tinaja Quadrangle; about 1 mile northeast of Cerro de Nuestra Senora; NAD 83, UTM 13—03 03 752 E—39 19 661 N.

A—0 to 3 inches; brown (7.5YR 5/4) very cobbly loam, dark brown (7.5YR 4/4) moist; weak thin platy structure; soft, very friable, slightly sticky and slightly plastic; many very fine roots; 25 percent cobbles and 30 percent gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bt1—3 to 12 inches; brown (7.5YR 5/4) clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard friable, sticky and plastic; many very fine roots; few very fine tubular pores; few fine clay films on faces of peds; 10 percent gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bt2—12 to 17 inches; light brown (7.5YR 6/4) clay loam, brown (7.5YR 5/4) moist; moderate medium subangular blocky structure; slightly hard, friable, sticky and plastic; common very fine roots; few very fine tubular pores; common thin, faint clay skins on faces of peds; slightly effervescent; slightly alkaline; clear smooth boundary.

Btk—17 to 21 inches; light brown (7.5YR 6/4) clay loam, brown (7.5YR 5/4) moist; moderate medium subangular blocky structure; slightly hard, very friable, sticky and plastic; few very fine roots; few very fine tubular pores; few thin faint clay skins on faces of peds; 10 percent gravel; violently effervescent; with common medium irregularly shaped seams and filaments of segregated calcium carbonate; moderately alkaline; gradual smooth boundary.

Bk1—21 to 40 inches; pink (7.5YR 7/4) clay loam, light brown (7.5YR 6/4) moist; weak fine subangular blocky structure; slightly hard, very friable, sticky and plastic; few very fine roots; few very fine tubular pores; 2 percent cobbles and 10 percent gravel; violently effervescent; many fine irregularly shaped filaments of segregated calcium carbonate; moderately alkaline; gradual smooth boundary.

Bk2—40 to 60 inches; pale brown (10YR 6/3) very gravelly sandy loam, yellowish brown (10YR 5/4) moist; massive; loose, nonsticky and nonplastic; few very fine roots; 40 percent gravel; violently effervescent; many fine irregularly shaped filaments of segregated calcium carbonate; slightly alkaline.

Range in Characteristics

Particle-size control section: 30 to 55 percent clay
Depth to calcic horizon: 20 to 40 inches

A horizon
Hue: 5YR, 7.5YR
Value: 3 to 6 dry, 3 to 5 moist
Chroma: 4 to 6 dry, 3 to 5 moist

Bt horizon
Hue: 2.5YR, 5YR, 7.5YR
Value: 4, 5 or 6 dry, 3, 4 or 5 moist
Chroma: 3 to 8, dry or moist

Bk horizon
Hue: 5YR, 7.5YR, 10YR
Value: 5 to 8 dry, 4 to 8 moist
Chroma: 1 to 6, dry or moist

Prieta Series

Map units: 2, 16
Depth class: shallow
Drainage class: well drained
Landform: lava flows and mesas
Parent material: eolian material and slope alluvium derived from basalt
Elevation: 5,600 to 7,300 feet (1,707 to 2,225 meters)
Slope: 3 to 15 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Clayey-skeletal, mixed, mesic Lithic Ustollic Haplargids

Typical Pedon

Prieta very stony loam, in an area of mapping unit 2, Clovis-Prieta-Silver association, 3 to 15 percent slopes; Sandoval County; Casa Salazar Quadrangle; on Prieta Mesa, 580 feet east and 2,600 feet north of the southwest corner of sec. 15, T. 14 N., R. 2 W. NAD 83, UTM 13—03 14 613 E—39 23 855 N.

A—0 to 3 inches; brown (10YR 5/3) very stony loam, dark brown (10YR 3/3) moist; weak fine granular structure; slightly hard, friable, slightly sticky and slightly plastic; many fine and very fine roots; 40 percent stones and 10 percent gravel; neutral; clear smooth boundary.
Bt1—3 to 10 inches; brown (7.5YR 5/4) very stony clay loam, dark brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; hard, firm, very sticky and very plastic; common fine and very fine roots; thin continuous clay films on faces of peds; 40 percent stones and 10 percent gravel; slightly alkaline; gradual smooth boundary.
Bt2—10 to 14 inches; brown (7.5YR 5/4) very stony clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common fine and very fine roots; thin continuous clay films on faces of peds; 25 percent stones and 10 percent gravel; moderately alkaline; clear smooth boundary.
Bk—14 to 19 inches; very pale brown (10YR 7/3) very stony clay loam, brown (10YR 5/3) moist; massive; slightly hard, friable, sticky and plastic; few fine roots; 40 percent stones and 10 percent gravel; common fine filaments of calcium carbonate; moderately alkaline; abrupt smooth boundary.
R—19 inches; basalt.

Range in Characteristics

Particle-size control section: 35 to 50 percent clay
Depth to basalt: 10 to 20 inches

A horizon
Hue: 10YR or 7.5YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 2 to 4
Texture: very stony loam or stony silt loam

Bt horizon
Hue: 10YR or 7.5YR
Value: 4 or 6 dry, 3 or 5 moist
Chroma: 2 to 4

Bk horizon
Hue: 10YR or 7.5YR
Value: 4 to 7 dry, 3 or 6 moist
Chroma: 2 to 4

Querencia Series

Map units: 13, 68, 231, 234
Depth class: very deep
Drainage class: well drained
Landform: alluvial fans, stream terraces, and valley sides
Parent material: fan alluvium and colluvium derived from sandstone and shale
Elevation: 5,700 to 6,900 feet (1,737 to 2,103 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, mesic Ustollic Camborthids

Typical Pedon

Querencia sandy clay loam, in an area of mapping unit 13, Sandoval-Querencia association, 2 to 7 percent slopes; Sandoval County; Sky Village NW Quadrangle; about 3/4 mile southeast of Trujillo Tank, Alamo Ranch; 1,100 feet south and 1,500 feet west of the northeast corner of sec. 4, T. 13 N., R. 1 W. NAD 83, UTM 13—03 23 504 E—39 17 713 N.

A—0 to 4 inches; light brownish gray (2.5Y 6/2) sandy clay loam, dark grayish brown (2.5Y 4/2) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common coarse, many fine and very fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.

Bw1—4 to 12 inches; light yellowish brown (2.5Y 6/4) clay loam, olive brown (2.5Y 4/4) moist; weak fine subangular blocky structure; hard, firm, slightly sticky and slightly plastic; many fine and very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.

Bw2—12 to 24 inches; pale yellow (2.5Y 7/4) loam, light olive brown (2.5Y 5/4) moist; weak medium subangular blocky structure; hard, firm, slightly sticky and slightly plastic; many fine and very fine roots; slightly effervescent; moderately alkaline; gradual smooth boundary.

Bk—24 to 60 inches; pale yellow (2.5Y 7/4) loam, light olive brown (2.5Y 5/4) moist; massive; hard, firm, slightly sticky and slightly plastic; few fine and very fine roots; slightly effervescent; calcium carbonate as few fine irregular masses; moderately alkaline; gradual smooth boundary.

Range in Characteristics

Calcium carbonate equivalent: less than 15 percent, calcareous in all parts
Content of rock fragments: 0 to 10 percent gravel
Reaction: slightly alkaline to moderately alkaline

A horizon
Hue: 2.5Y or 10YR;
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: fine sandy loam, loam, or sandy clay loam

Bw horizon
Hue: 2.5Y or 10YR;
Value: 4 to 7 dry, 4 or 5 moist
Chroma: 2 to 6
Texture: loam, sandy clay loam, or clay

Bk horizon
Hue: 2.5Y or 10YR
Value: 4 to 7 dry, 4 or 5 moist
Chroma: 2 to 6
Texture: fine sandy loam and loam

Redondo Series

Map units: 85, 86, 87
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes
Parent material: colluvium derived from tuff
Elevation: 8,700 to 11,000 feet (2,652 to 3,353 meters)
Slope: 15 to 80 percent
Climatic data:
Mean annual precipitation: 25 to 30 inches (635 to 762 millimeters)
Mean annual air temperature: 38 to 42 degrees F. (3.3 to 5.6 degrees C.)
Frost-free period: 45 to 60 days

Taxonomic class: Loamy-skeletal, mixed Typic Cryoboralfs

Typical Pedon

Redondo coarse sandy loam, in an area of mapping unit 85, Redondo coarse sandy loam; 15 to 35 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about 3 miles northwest of Baca Location No. 1 Headquarters; unsectionized; NAD 83, UTM 13—03 63 260 E—39 72 828 N.

A—0 to 2 inches; grayish brown (10YR 5/2) coarse sandy loam, very dark grayish brown (10YR 3/2) moist; weak medium granular structure; soft, very friable, slightly sticky and slightly plastic; many very fine and few medium roots; slightly acid; clear smooth boundary.

E1—2 to 7 inches; light brownish gray (10YR 6/2) coarse sandy loam, dark grayish brown (10YR 4/2) moist; moderate medium platy and weak fine subangular blocky structure; slightly hard, friable, slightly sticky and plastic; common very fine and few medium roots; few thin silt coatings on faces of peds; slightly acid; clear smooth boundary.

E2—7 to 15 inches; light gray (10YR 7/2) coarse sandy loam, brown (10YR 5/3) moist; weak medium platy and weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common very fine and few medium roots; very few very thin silt coating on faces of peds; 1 percent cobbles and 2 percent gravel; medium acid; clear wavy boundary.

BE—15 to 22 inches; pink (7.5YR 7/4) coarse sandy loam, brown (7.5YR 5/4) moist; weak fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine and very fine roots; few thin silt coatings on faces of peds; 3 percent gravel; medium acid; clear wavy boundary.

Bt1—22 to 29 inches; light gray (10YR 7/2) gravelly coarse sandy loam, brown (10YR 5/3) moist; moderate fine and medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few very fine roots; common moderately thick clay films on faces of peds; 25 percent gravel; medium acid; gradual wavy boundary.

Bt2—29 to 38 inches; light brown (7.5YR 6/4) very gravelly coarse sandy loam, brown (7.5YR 4/4) moist; weak medium and coarse subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; few fine medium and coarse roots; common moderately thick clay films on rock fragments and bridging sand grains; 5 percent stones, 10 percent cobbles and 30 percent gravel; medium acid; diffuse wavy boundary.

Bt3—38 to 54 inches; light brown (7.5YR 6/4) extremely gravelly coarse sandy loam, brown (7.5YR 4/4) moist; weak medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine and medium roots; common moderately thick clay films on rock fragments and bridging sand grains; 10 percent stones, 10 percent cobbles, and 60 percent gravel; medium acid; diffuse wavy boundary.

Bt4—54 to 60 inches; light brown (7.5YR 6/4) extremely cobbly coarse sandy loam, brown (7.5YR 4/4) moist; massive; hard, firm, slightly sticky and slightly plastic; few medium roots; few moderately thick clay films on rock fragments and bridging sand grains; 15 percent stones, 25 percent cobbles, and 50 percent gravel; medium acid; diffuse wavy boundary.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay

A horizon

Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 2 or 3, dry or moist
Texture: cobbly coarse sandy loam, coarse sandy loam, and cobbly loam

E horizon

Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 4 to 6 moist
Chroma: 1 to 4, dry or moist
Texture: coarse sandy loam, very cobbly coarse sandy loam, or extremely cobbly coarse sandy loam

B horizon
Hue: 7.5YR or 10YR
Value: 4 to 8 dry, 4 or 5 moist
Chroma: 2 to 4, dry or moist
Texture: gravelly coarse sandy loam, very gravelly coarse sandy loam, very cobbly coarse sandy loam, or extremely cobbly coarse sandy loam

Royosa Series

Map units: 312, 314, 321
Depth class: very deep
Drainage class: somewhat excessively drained and excessively drained
Landform: dunes
Parent material: eolian sands derived from sandstone
Elevation: 5,600 to 6,700 feet (1,707 to 2,042 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Mixed, mesic Typic Ustipsamments

Typical Pedon

Royosa sand, in an area of mapping unit 312, Royosa sand, 1 to 8 percent slopes; Sandoval County; Jemez Pueblo Quadrangle; about 4 miles north of the Zia Pueblo; 2,550 feet east and 2,000 feet north of the southwest corner of sec. 32, T. 16 N., R. 3 E. NAD 83, UTM 13—03 50 811 E—39 37 468 N.

A—0 to 5 inches; very pale brown (10YR 7/3) sand, brown (10YR 5/3) moist; single grain; loose, nonsticky and nonplastic; slightly alkaline; clear smooth boundary.
C1—5 to 16 inches; brown (7.5YR 5/4) sand, brown (7.5YR 4/4) moist; single grain; loose, nonsticky and nonplastic; common medium and coarse roots; slightly alkaline; gradual smooth boundary.
C2—16 to 60 inches; brownish yellow (10YR 6/6) loamy sand, yellowish brown (10YR 5/6) moist; single grain; loose, nonsticky and nonplastic; slightly alkaline.

Range in Characteristics

Reaction: neutral to moderately alkaline

A horizon
Hue: 10YR to 5YR
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 3 to 6
Texture: sand or fine sand

C horizon
Hue: 10YR to 5YR
Value: 4 to 7 dry, 3 to 6 moist
Chroma: 3 to 6
Texture: sand, fine sand, or loamy sand

Saido Series

Map unit: 110
Depth class: very deep
Drainage class: well drained
Landform: cuestas, fans, mesas, and knolls
Parent material: slope alluvium derived from silty gypsiferous material
Elevation: 5,300 to 6,000 feet (1,615 to 1,829 meters)
Slope: 5 to 40 percent
Climatic data:
Mean annual precipitation: 10 to 12 inches (254 to 305 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Coarse-silty, gypsic, mesic Typic Gypsiorthids

Typical Pedon

Saido silt loam, in an area of mapping unit 110, Rock outcrop-Saido complex, 5 to 40 percent slopes; Sandoval County; San Ysidro Quadrangle; on the gypsum mine haul road about 2 miles south of San Ysidro; 1,500 feet north and 1,800 feet east of the southwest corner of sec. 13, T. 15 N., R. 1 E. NAD 83, UTM 13—03 37 730 E—39 32 751 N.

A—0 to 5 inches; very pale brown (10YR 8/3) silt loam, pink (7.5YR 7/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; few fine and coarse roots; common fine interstitial pores; strongly effervescent; moderately alkaline; clear smooth boundary.

By1—5 to 9 inches; white (10YR 8/2) silt loam, very pale brown (10YR 7/3) moist; weak medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; few fine and coarse roots; common fine tubular pores; many medium masses of gypsum crystals; violently effervescent; moderately alkaline; clear smooth boundary.

By2—9 to 15 inches; white (10YR 8/2) silt loam, white (10YR 8/2) moist; massive; soft, very friable, nonsticky and nonplastic; many medium masses of gypsum crystals; violently effervescent; moderately alkaline; clear smooth boundary.

By3—15 to 25 inches; white (10YR 8/2) silt loam, white (10YR 8/2) moist; massive; slightly hard, very friable, nonsticky and nonplastic; many medium masses of gypsum crystals; violently effervescent; moderately alkaline; clear smooth boundary.

C—25 to 60 inches; pink (7.5YR 8/4) loam, pink (7.5YR 7/4) moist; massive; soft, very friable, nonsticky and nonplastic; few medium masses of gypsum crystals; violently effervescent; moderately alkaline.

Range in Characteristics

Depth to gypsic horizon: 2 to 5 inches

A horizon
Hue: 5YR, 7.5YR, or 10YR
Value: 5 to 8 dry, 4 to 7 moist
Chroma: 3 or 4

B and C horizons
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 5 to 7 moist
Chroma: 1 to 4

San Mateo Series

Map units: 114, 170
Depth class: very deep
Drainage class: well drained
Landform: flood plains, alluvial fans, and valley sides
Parent material: stream alluvium from mixed sources
Elevation: 5,500 to 6,800 feet (1,676 to 2,073 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-loamy, mixed, calcareous, mesic Ustic Torrifluvents

Typical Pedon

San Mateo loam, in an area of mapping unit 170, San Mateo loam, 0 to 3 percent slopes; Sandoval County; San Ysidro Quadrangle; about 5 miles southwest of San Ysidro; 200 feet south and 1,500 feet east of the center of sec. 27, T. 15 N., R. 1 E. NAD 83, UTM 13—03 35 171 E—39 29 854 N.

A—0 to 2 inches; pale brown (10YR 6/3) loam, brown (10YR 5/3) moist; weak fine granular structure; soft, very friable, nonsticky and slightly plastic; common medium and fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C1—2 to 10 inches; dark yellowish brown (10YR 4/4) clay loam, dark yellowish brown (10YR 3/4) moist; massive; soft, friable, slightly sticky and slightly plastic; common medium, fine and very fine roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C2—10 to 23 inches; light yellowish brown (10YR 6/4) clay loam, yellowish brown (10YR 5/4) moist; massive; slightly hard, firm, sticky and plastic; common fine and very fine roots; few medium roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C3—23 to 32 inches; light yellowish brown (10YR 6/4) clay loam, yellowish brown (10YR 5/4) moist; massive; slightly hard, firm, sticky and plastic; few fine and very fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C4—32 to 54 inches; yellowish brown (10YR 5/4) clay loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, firm, sticky and plastic; few very fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.
C5—54 to 60 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; massive; slightly hard, firm, sticky and plastic; strongly effervescent; strongly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 10YR or 2.5Y
Value: 5 or 6 dry, 3 to 5 moist
Chroma: 2 to 6 dry and moist
Texture: sandy loam and loam

C horizon
Hue: 10YR or 2.5Y
Value: 5 or 6 dry; 3 to 5, moist
Chroma: 2 to 6
Texture: stratified sandy loam, loam, silty clay loam, and clay loam
Sodicity: SAR of 5 to 30

Sandoval Series

Map units: 13, 15, 67, 230, 235
Depth class: shallow
Drainage class: well drained
Landform: hills and ridges
Parent material: slope alluvium derived from shale
Elevation: 5,800 to 7,000 feet (1,768 to 2,134 meters)
Slope: 1 to 30 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy, mixed, calcareous, mesic, shallow Ustic Torriorthents

Typical Pedon

Sandoval fine sandy loam, in an area of mapping unit 13, Sandoval-Querencia association, 2 to 7 percent slopes; Sandoval County; Sky Village NW Quadrangle; about 5 miles south of the Alamo Ranch headquarters; 1,100 feet south and 2,700 feet east of the northwest corner of sec. 4, T. 13 N., R. 1 W. NAD 83, UTM 13—03 23 157 E—39 17 735 N.

A1—0 to 2 inches; light yellowish brown (10YR 6/4) fine sandy loam, dark yellowish brown (10YR 4/4) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; common fine and very fine roots; slightly effervescent; strongly alkaline; abrupt smooth boundary.
A2—2 to 6 inches; light gray (2.5YR 7/2) clay loam, light olive brown (2.5YR 5/4) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; common fine and very fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—6 to 10 inches; light brownish gray (2.5YR 6/2) clay loam, grayish brown (2.5YR 5/2) moist; massive; hard, firm, sticky and plastic; common fine and very fine and few medium roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C2—10 to 15 inches; light brownish gray (2.5YR 6/2) clay loam, dark grayish brown (2.5YR 4/2) moist; massive; hard, firm, sticky and plastic; few fine roots; slightly effervescent; moderately alkaline; clear smooth boundary.
Cr—15 inches; soft calcareous shale.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay
Content of gypsum: 5 to 10 percent
Salinity: EC of 2 to 4
Sodicity: SAR of 8 to 13
Depth to paralithic contact: 10 to 20 inches

A horizon
Hue: 10YR or 2.5Y
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 6
Texture: loam, clay loam, and fine sandy loam

C horizon
Hue: 2.5Y or 5Y
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 4

Santa Fe Series

Map units: 409, 419
Depth class: very shallow to shallow
Drainage class: well drained
Landform: mountain slopes
Parent material: slope alluvium and residuum derived from granite
Elevation: 6,400 to 8,400 feet (1,951 to 2,560 meters)
Slope: 15 to 70 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy-skeletal, mixed, mesic Lithic Argiustolls

Typical Pedon

Santa Fe very gravelly sandy loam, in an area of mapping unit 409, Santa Fe very gravelly sandy loam, 15 to 40 percent slopes; Sandoval County; Gilman Quadrangle; about 8 miles west of the Jemez Pueblo; 1,300 feet north and 350 feet west of the SE corner of sec. 8, T. 16 N., R. 1 E. NAD 83, UTM 13—03 32 465 E—39 44 119 N

A—0 to 3 inches; dark reddish gray (5YR 4/2) very gravelly sandy loam, dark reddish brown (5YR 3/2) moist; moderate fine granular structure; soft, friable, nonsticky and nonplastic; many very fine roots; common very fine tubular pores; 2 percent stones, 3 percent cobbles and 40 percent gravel; neutral; clear smooth boundary.
Bt—3 to 8 inches; weak red (2.5YR 4/2) very gravelly sandy clay loam, dusky red (2.5YR 3/2) moist; strong fine angular block structure; slightly hard, firm, sticky and plastic, common very fine roots, many very fine tubular pores, 10 percent cobbles and 35 percent gravel; many thin clay films on faces of peds; neutral, clear smooth boundary.
2R—8 inches; granite.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay
Depth to bedrock: 8 to 20 inches

A horizon
Hue: 5YR to 10YR
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 2 or 3
Texture: gravelly sandy loam or extremely cobbly coarse sandy loam

Bt horizon
Hue: 2.5YR to 7.5YR
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 2 or 3

Sedgran Series

Map unit: 201
Depth class: very shallow to shallow
Drainage class: excessively drained
Landform: mountain slopes
Parent material: colluvium derived from granite and sandstone
Elevation: 5,800 to 8,000 feet (1,768 to 2,438 meters)
Slope: 25 to 55 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Sandy-skeletal, mixed, mesic Lithic Ustic Torriorthents

Typical Pedon

Sedgran extremely gravelly loamy coarse sand, in an area of mapping unit 201, Rock outcrop-Sedgran association, 25 to 55 percent slopes; Sandoval County; Alameda Quadrangle; about 3 1/4 miles east of Interstate Highway 25 and 1/8 miles north of the Sandoval-Bernalillo county line on the Sandia Pueblo Indian Reservation; 1,300 feet east and 450 of north of the southwest corner of sec. 34, T. 12 N., R. 4 E. NAD 83, UTM 13—03 62 490 E—38 98 152 N.

A—0 to 4 inches; yellowish brown (10YR 5/4) extremely gravelly loamy coarse sand, dark yellowish brown (10YR 3/4) moist; moderate medium granular structure; loose, very friable, nonsticky and nonplastic; many fine roots; 20 percent cobbles and 45 percent gravel; neutral; clear wavy boundary.
C—4 to 13 inches; reddish yellow (7.5YR 6/6) and yellowish brown (7.5YR 5/4) very gravelly loamy coarse sand, brownish yellow (7.5YR 5/6) and dark yellowish brown (7.5YR 4/4) moist; massive; slightly hard, very friable, nonsticky and nonplastic; few fine roots; 5 percent cobbles and 40 percent gravel; slightly alkaline; diffuse wavy boundary.
2R—13 inches; granite bedrock.

Range in Characteristics

Particle-size control section: 5 to 10 percent clay
Depth to lithic contact: 6 to 20 inches

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6

C horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 4 to 6

Sedillo Series

Map units: 200, 208
Depth class: very deep
Drainage class: well drained
Landform: bajadas, fan terraces, and stream terraces
Parent material: gravelly fan alluvium derived from mixed sources
Elevation: 5,100 to 6,500 feet (1,554 to 1,981 meters)
Slope: 5 to 55 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy-skeletal, mixed, mesic Ustollic Haplargids

Typical Pedon

Sedillo very gravelly fine sandy loam, in an area of mapping unit 208, Sedillo very gravelly fine sandy loam, 25 to 55 percent slopes; Sandoval County; San Felipe Pueblo Quadrangle; about one mile southeast of the San Felipe Pueblo, about 2000 feet south and 300 feet west of NE corner of sec. 29, T. 14 N., R. 5 E. NAD 83, UTM 13—03 70 512 E—39 19 951 N.

A—0 to 2 inches; brown (10YR 4/3) very gravelly fine sandy loam, dark brown (10YR 3/3) moist; weak thin platy structure; soft, very friable, nonsticky and nonplastic; many very fine roots, 55 percent gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bt—2 to 8 inches; brown (10YR 4/3) very gravelly sandy clay loam, dark yellowish brown (10YR 3/4) moist; moderate medium and fine subangular blocky structure; soft, friable, slightly sticky and slightly plastic; many very fine roots; common very fine tubular pores; few thin clay films on faces of peds; 50 percent gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bk1—8 to 12 inches; yellowish brown (10YR 5/4) very gravelly sandy loam, dark yellowish brown (10YR 4/4) moist; medium and fine subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common very fine roots; many very fine tubular pores; 50 percent gravel; slightly effervescent; few coatings on undersides of rock fragments of calcium carbonate; slightly alkaline; gradual smooth boundary.

Bk2—12 to 60 inches; very pale brown (10YR 8/3) extremely gravelly sandy loam, light yellowish brown (10YR 6/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few very fine roots; many very fine tubular pores; 60 percent gravel; violently effervescent; undersides of rock fragments coated with calcium carbonate; slightly alkaline.

Range in Characteristics

Particle-size control section: 20 to 35 percent clay

A horizon
Hue: 5YR to 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 or 4
Texture: very cobbly sandy loam and very gravelly fine sandy loam

Bt horizon
Hue: 10YR to 5YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 3 to 6

Bk horizon
Hue: 5YR to 10YR
Value: 5 to 8 dry, 3 to 7 moist
Chroma: 2 to 6
Texture: extremely gravelly coarse sandy loam, very gravelly sandy loam, and extremely gravelly sandy loam

Sedmar Series

Map unit: 146
Depth class: very shallow to shallow
Drainage class: excessively drained
Landform: dipslopes of cuestas and ridges
Parent material: slope alluvium and residuum derived from sandstone
Elevation: 7,000 to 8,000 feet (2,134 to 2,438 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Sandy, mixed, frigid Lithic Ustorthents

Typical Pedon

Sedmar loamy sand, in an area of mapping unit 146, Sedmar loamy sand, 1 to 15 percent slopes; Sandoval County; Cuba Quadrangle; about 1 mile north of Cuba; 2,600 feet south and 200 feet west of the northeast corner of sec. 17, T. 21 N., R. 1 W. NAD 83, UTM 13—03 23 734 E—39 91 047 N.

A—0 to 3 inches; light yellowish brown (10YR 6/4) loamy sand, brown (10YR 4/3) moist; single grain; loose, nonsticky and nonplastic; neutral; abrupt smooth boundary.
C1—3 to 13 inches; brownish yellow (10YR 6/6) and brown (10YR 5/3) sandy loam, brown (10YR 4/3) and yellowish brown (10YR 5/6) moist; weak fine subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; few common distinct yellowish brown (10YR 5/8) iron stains; neutral; clear smooth boundary.
C2—13 to 18 inches; brownish yellow (10YR 6/6) loamy sand, brownish yellow (10YR 6/6) moist; single grain; loose, nonsticky and nonplastic; neutral; abrupt smooth boundary.
2R—18 inches; sandstone.

Range in Characteristics

Particle-size control section: 5 to 15 percent clay
Depth to lithic contact: 6 to 20 inches

A and C horizons
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 3 to 6
Texture: loamy sand stratified with layers of sandy loam

Sheppard Series

Map units: 145, 183, 191
Depth class: very deep
Drainage class: somewhat excessively drained
Landform: dunes, alluvial fans, benches, structural benches, terraces, and stream terraces
Parent material: eolian sands derived from sandstone
Elevation: 5,000 to 6,000 feet (1,524 to 1,829 meters)
Slope: 1 to 40 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Mixed, mesic Typic Torripsamments

Typical Pedon

Sheppard loamy fine sand, in an area of mapping unit 191, Sheppard loamy fine sand, 3 to 8 percent slopes; Sandoval County; Bernalillo Quadrangle; unsectionized; NAD 83, UTM 13—03 55 559 E—39 06 478 N.

A—0 to 3 inches; light brown (7.5YR 6/4) loamy fine sand, brown (7.5YR 4/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; common fine and very fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C1—3 to 27 inches; strong brown (7.5YR 5/6) loamy fine sand, brown (7.5YR 4/4) moist; single grain; loose, nonsticky and nonplastic; few fine and medium roots; slightly effervescent; moderately alkaline; clear smooth boundary.
C2—27 to 60 inches; pink (7.5YR 7/4) loamy fine sand, brown (7.5YR 5/4) moist; single grain; loose, nonsticky and nonplastic; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 3 to 10 percent clay

A horizon
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4

C horizon
Hue: 2.5YR to 7.5YR
Value: 5 to 7 (4 to 6 moist)
Chroma: 3 to 6
Texture: loamy fine sand, sand, or loamy sand

Silver Series

Map units: 1, 2
Depth class: very deep
Drainage class: well drained
Landform: mesas, fan terraces, hills, and plateaus
Parent material: eolian material and slope alluvium derived from shale and sandstone
Elevation: 5,600 to 7,300 feet (1,707 to 2,225 meters)
Slope: 1 to 8 percent

Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine, mixed, mesic Ustollic Haplargids

Typical Pedon

Silver loam, in an area of mapping unit 1, Silver-Clovis loams, 1 to 7 percent slopes; Sandoval County; Casa Salazar Quadrangle; on Mesa Prieta; 1,300 feet north and 150 feet east of the center of sec. 9, T. 14 N., R. 2 W. NAD 83, UTM 13—03 13 700 E—39 25 879 N.

A—0 to 4 inches; pale brown (10YR 6/3) loam, brown (10YR 4/3) moist; weak thick platy structure parting to moderate medium granular; slightly hard, friable, sticky and plastic; common fine and very fine roots; neutral; clear smooth boundary.
Bt1—4 to 8 inches; light brown (7.5YR 6/4) silty clay loam, brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; slightly hard, friable, sticky and plastic; common fine and very fine roots; few thin clay films on faces of peds; slightly alkaline; clear smooth boundary.
Bt2—8 to 20 inches; brown (7.5YR 5/2) silty clay loam, brown (7.5YR 4/2) moist; moderate fine and medium subangular blocky structure; hard, firm, very sticky and very plastic; common fine and very fine roots; continuous thick clay films on faces of peds; slightly alkaline; gradual smooth boundary.
Bt3—20 to 39 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; moderate medium subangular blocky structure; hard, firm, very sticky and very plastic; few fine and very fine roots; many thick clay films on faces of peds; slightly alkaline; clear smooth boundary.
C—39 to 60 inches; brown (7.5YR 5/4) clay loam, dark brown (7.5YR 4/4) moist; massive; hard, firm, very sticky and very plastic; slightly alkaline.

Range in Characteristics

Particle-size control section: 35 to 50 percent clay

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4

Bt and Btk horizons
Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 3 to 6 moist
Chroma: 2 to 4
Texture: clay loam or silty clay loam

Bk and C horizons (where present)
Hue: 7.5YR or 10YR
Value: 6 to 8 dry, 5 to 7 moist
Chroma: 2 to 4
Texture: clay loam and silty clay loam

Skyvillage Series

Map units: 64, 190, 230
Depth class: very shallow to shallow
Drainage class: well drained

Landform: breaks, structural benches, dipslopes of cuestas, summits of mesas and hills, and ridges
Parent material: slope alluvium derived from sandstone
Elevation: 5,800 to 6,400 feet (1,768 to 1,951 meters)
Slope: 3 to 40 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy, mixed, calcareous, mesic Lithic Ustic Torriorthents

Typical Pedon

Skyvillage fine sandy loam, in an area of mapping unit 190, Zia-Skyvillage-Rock outcrop complex, 5 to 40 percent slopes; Sandoval County; Sky Village NW Quadrangle; about 6 miles northeast of the Alamo Ranch headquarters; 700 feet north and 600 feet east of the center of sec. 22, T. 14 N., R. 1 W. NAD 83, UTM 13—03 25 078 E—39 22 260 N.

A—0 to 2 inches; pale yellow (2.5Y 7/4) fine sandy loam, light olive brown (2.5Y 5/4) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; few fine roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C1—2 to 11 inches; light gray (2.5Y 7/2) fine sandy loam, light olive brown (2.5Y 5/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; common fine and very fine roots; slightly effervescent; moderately alkaline; clear wavy boundary.
C2—11 to 16 inches; light gray (2.5Y 7/2) fine sandy loam, light olive brown (2.5Y 5/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; few fine and very fine roots; 10 percent gravel; slightly effervescent; slightly alkaline.
2R—16 inches; sandstone.

Range in Characteristics

Particle-size control section: 10 to 27 percent clay
Depth to bedrock: 6 to 20 inches

A and C horizons
Hue: 2.5Y to 7.5YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 6
Texture: sandy loam or fine sandy loam

Sparank Series

Map units: 236, 237
Depth class: very deep
Drainage class: well drained
Landform: stream terraces, alluvial fans, valley sides, and flood plains
Parent material: stream alluvium derived from sandstone and shale
Elevation: 5,500 to 6,400 feet (1,676 to 1,951 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine, mixed, calcareous, mesic Ustic Torrifluvents

Typical Pedon

Sparank clay loam, in an area of mapping unit 236, Sparank clay loam, moderately saline, sodic, 0 to 1 percent slopes; Sandoval County; Holy Ghost Spring Quadrangle; about 3 miles northeast of San Luis; unsectionized; NAD 83, UTM 13—03 19 302 E—39 55 938 N.

A—0 to 2 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; moderate fine granular structure; slightly hard, friable, sticky and plastic; few fine roots; slightly effervescent; strongly alkaline; clear smooth boundary.
C1—2 to 10 inches; brown (10YR 5/3) silty clay, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; common fine roots; slightly effervescent; strongly alkaline; gradual smooth boundary.
C2—10 to 24 inches; brown (10YR 4/3) silty clay, brown (10YR 4/3) moist; massive; hard, firm, sticky and plastic; common medium roots; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C3—24 to 40 inches; pale brown (10YR 6/3) silty clay loam with thin strata of silt loam, brown (10YR 5/3) moist; massive; hard, firm, slightly sticky and slightly plastic; strongly effervescent; moderately alkaline; abrupt smooth boundary.
C4—40 to 44 inches; dark grayish brown (10YR 4/2) silty clay, dark grayish brown (10YR 4/2) moist; massive; hard, firm, sticky and plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C5—44 to 60 inches; pale brown (10YR 6/3) silty clay, brown (10YR 5/3) moist; massive; hard, firm, sticky and plastic; slightly effervescent; strongly alkaline.

Range in Characteristics

Sodicity: SAR less than 13, typically
Salinity: EC of 4 to 8, typically

A horizon
Hue: 10YR to 5Y
Value: 4 to 6 moist, 3 to 6 dry
Chroma: 1 to 4
Texture: sandy clay loam, silt loam, clay loam, silty clay loam, silty clay, or clay
Reaction: moderately alkaline or strongly alkaline

C horizon
Hue: 10YR to 5Y
Value: 3 to 7 dry or moist
Chroma: 1 to 4
Texture: clay, silty clay, silty clay loam, or clay loam. Usually contains thin strata of silt loam or loamy sand.
Reaction: moderately alkaline to very strongly alkaline

Note: Some pedons have few to many fine prominent relict mottles of 5Y or 2.5Y 4/6 to 4/8 below 20 inches.

Sparham Series

Map units: 18, 24, 51, 102, 320
Depth class: very deep
Drainage class: well drained, somewhat poorly drained
Landform: alluvial fans, flood plains, and valley sides
Parent material: fan and stream alluvium derived from sandstone and shale
Elevation: 5,000 to 7,500 feet (1,524 to 2,286 meters)

Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 50 to 55 degrees F. (10.0 to 12.8 degrees C.)
Frost-free period: 110 to 160 days

Taxonomic class: Fine, mixed, calcareous, mesic Typic Ustifluvents

Typical Pedon

Sparham clay, in an area of mapping unit 102, Sparham clay loam, 1 to 3 percent slopes; Sandoval County; Cuba Quadrangle; about 1 mile northwest of Cuba; 1,500 feet south and 1,100 feet east of the northwest corner of sec. 20, T. 21 N., R. 1 W. NAD 83, UTM 13—03 22 490 E—39 89 805 N.

A—0 to 7 inches; grayish brown (10YR 5/2) clay loam, dark grayish brown (10YR 4/2) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; many very fine and common fine roots; neutral; clear smooth boundary.
C1—7 to 20 inches; light brownish gray (10YR 6/2) clay loam, dark gray (10YR 4/1) moist; common medium prominent strong brown (7.5YR 5/8) mottles; massive; very hard, very firm, very sticky and very plastic; common very fine roots; slightly effervescent; slightly alkaline; clear smooth boundary.
C2—20 to 29 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; common fine prominent strong brown (7.5YR 5/8) mottles; massive; very hard, very firm, very sticky and very plastic; few very fine roots; slightly effervescent; moderately alkaline; gradual smooth boundary.
C3—29 to 47 inches; very pale brown (10YR 7/4) silty clay loam, yellowish brown (10YR 5/4) moist; few fine prominent strong brown (7.5YR 5/8) mottles; massive; very hard, very firm, very sticky and very plastic; few very fine roots; slightly effervescent; slightly alkaline; clear smooth boundary.
C4—47 to 53 inches; very pale brown (10YR 7/4) clay loam, yellowish brown (10YR 5/4) moist; common medium prominent strong brown (7.5YR 5/8) mottles; massive; very hard, very firm, very sticky and very plastic; slightly effervescent; moderately alkaline; abrupt smooth boundary.
C5—53 to 60 inches; dark gray (10YR 4/1) clay loam, very dark gray (10YR 3/1) moist; massive; very hard, very firm, very sticky and very plastic; 10 percent fine gravel; moderately alkaline.

Range in Characteristics

Particle-size control section: 35 to 59 percent clay
Redoximorphic features: concentrations and depletions close to the surface are relict features
Depth to salts: 20 to 35 inches, when present
Depth to water table: typically 6 feet or greater (4 to 5 feet in some pedons)

A horizon
Hue: 10YR, 2.5Y or 5Y
Value: 4 to 6 dry, 3 to 6 moist. When crushed, moist value is less than 3.5, thickness is less than 7 inches.
Chroma: 1 to 4 dry
Texture: clay loam, silty clay loam, silt loam, or clay

C horizon
Hue: 10YR, 2.5Y or 5Y
Value: 3 to 7 dry, 3 to 6 moist
Chroma: 1 to 4 dry and 1 to 6 moist

Texture: stratified clay loam, silty clay loam, silty clay, or clay (there are strata of textures as coarse as loamy sand)
Reaction: slightly alkaline to strongly alkaline
Sodicity: SAR of 5 to 30
Salinity: EC of 2 to 16, typically

Note: The Sparham component in map unit 51 is somewhat poorly drained and outside the range in characteristics of the series. The component is a taxadjunct to the series.

Stumble Series

Map unit: 106
Depth class: very deep
Drainage class: somewhat excessively drained
Landform: alluvial fans, fan aprons, fan remnants, and inset fans
Parent material: eolian sands derived from sandstone
Elevation: 5,000 to 5,600 feet (1,524 to 1,707 meters)
Slope: 1 to 40 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Mixed, mesic Typic Torripsamments

Typical Pedon

Stumble very gravelly fine sandy loam in an area of map unit 106, Stumble association, 1 to 40 percent slopes; Sandoval County; Bernalillo Quadrangle; about 1.5 miles northeast of the Sandia Indian Pueblo; 1,400 feet east and 401 feet north of the southwest corner of sec. 17, T. 12 N., R. 4 E. NAD 83, UTM 13—03 59 375 E—39 03 017 N.

A—0 to 4 inches; pale brown (10YR 6/3) very gravelly fine sandy loam, brown (10YR 4/3) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine and few medium roots; 45 percent pebbles; slightly effervescent; moderately alkaline; clear smooth boundary.
Bw—4 to 10 inches; brown (7.5YR 5/4) gravelly fine sandy loam, dark brown (7.5YR 4/4) moist; weak medium subangular blocky structure; slightly hard, friable, nonsticky and nonplastic; common fine roots; 25 percent pebbles; slightly effervescent; mildly alkaline; gradual wavy boundary.
C1—10 to 24 inches; very pale brown (10YR 7/4) loamy sand, yellowish brown (10YR 5/4) moist; massive; slightly hard, very friable, nonsticky and nonplastic; common fine roots; 10 percent pebbles; slightly effervescent; moderately alkaline; gradual wavy boundary.
C2—24 to 60 inches; very pale brown (10YR 7/3) gravelly coarse sand, brown (10YR 4/3) moist; single grain; loose, nonsticky and nonplastic; few fine roots; 20 percent pebbles; slightly effervescent; moderately alkaline.

Range in Characteristics

A horizon
Value: 6 or 7 dry, 4 or 5 moist
Chroma: 2 or 3, dry or moist
Reaction: neutral to moderately alkaline
Texture: gravelly loamy sand or very gravelly fine sandy loam

Bw horizon (when present)
Texture: gravelly fine sandy loam or loamy sand

C horizons
Hue: 10YR or 2.5Y
Value: 6 or 7 dry, 4 or 5 moist
Chroma: 2 or 3, dry or moist
Texture: loamy sand or gravelly coarse sand, with strata of fine sand and sand

Teco Series

Map unit: 399
Depth class: very deep
Drainage class: well drained
Landform: cuestas and hills
Parent material: slope alluvium derived from sandstone and shale
Elevation: 5,900 to 7,000 feet (1,798 to 2,134 meters)
Slope: 8 to 40 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine, mixed, mesic Aridic Haplustalfs

Typical Pedon

Teco very cobbly fine sandy loam, in an area of mapping unit 399; Cucho-Teco complex, 8 to 40 percent slopes; Sandoval County; Holy Ghost Spring Quadrangle; about 3 miles south of the Jemez-Zia Pueblo boundary along State Highway 44 then east .25 mile; unsectionized; NAD 83, UTM 13—03 27 701 E—39 48 805 N.

A—0 to 1 inch; yellowish brown (10YR 5/4) very cobbly fine sandy loam, dark brown (10YR 4/3) moist; weak fine granular structure; loose, very friable, nonsticky and nonplastic; many fine and few medium roots; 20 percent cobbles, 15 percent gravels; slightly alkaline; abrupt smooth boundary.

Bt1—1 inch to 7 inches; reddish brown (5YR 5/4) sandy clay, reddish brown (5YR 4/4) moist; moderate medium subangular blocky structure parting to moderate fine granular; hard, firm, sticky and plastic; common fine roots; few fine tubular pores; few fine clay films lining pores; slightly alkaline; clear smooth boundary.

Bt2—7 to 23 inches; reddish yellow (7.5YR 6/6) clay, strong brown (7.5YR 5/6) moist; moderate fine subangular and angular blocky structure; hard, firm, very sticky and very plastic; common fine roots; common fine tubular pores; few thin faint dark brown (7.5YR 4/4) clay skins on vertical faces of peds; slightly effervescent; slightly alkaline; gradual wavy boundary.

Btk—23 to 40 inches; pink (7.5YR 7/4) clay, light brown (7.5YR 6/4) moist; massive; hard, firm, sticky and plastic; few fine roots; strongly effervescent; few fine clay films on faces of peds; common medium irregularly shaped segregated soft masses of calcium carbonate; slightly alkaline; clear wavy boundary.

2C—40 to 45 inches; light yellowish brown (10YR 6/4) very gravelly fine sandy loam, yellowish brown (10YR 5/4) moist; massive; loose, nonsticky and nonplastic; strongly effervescent; 30 percent gravel, 10 percent cobbles; slightly alkaline; gradual wavy boundary.

3Bkb—45 to 60 inches; pale yellow (5Y 8/3) channery sandy clay loam, pale yellow (5Y 7/3) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; 25 percent soft shale fragments; strongly effervescent; many large, white (5YR 8/2) soft masses of calcium carbonate in rounded pockets and vertical seams; slightly alkaline.

Range in Characteristics

Particle-size control section: 35 to 45 percent clay
Depth to calcic horizon: 20 to 40 inches

A horizon
Hue: 10YR to 5YR
Value: 5 to 7 dry, 3 to 6 moist
Chroma: 3 or 4

Bt horizon
Hue: 7.5YR to 2.5YR
Value: 4 to 7 dry, 3 to 7 moist
Chroma: 2 to 6

Bk horizon
Hue: 7.5YR to 2.5YR
Value: 5 to 7 dry, 3 to 7 moist
Chroma: 4 to 8

Tijeras Series

Map units: 109, 112
Depth class: very deep
Drainage class: well drained
Landform: fan remnants and ridges
Parent material: fan alluvium derived from granite
Elevation: 5,100 to 5,600 feet (1,554 to 1,707 meters)
Slope: 1 to 6 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Fine-loamy, mixed, mesic Typic Haplargids

Typical Pedon

Tijeras gravelly fine sandy loam, in an area of mapping unit 109; Embudo-Tijeras association, 1 to 9 percent slopes; Sandoval County; Alameda Quadrangle; located about 2 miles east of interstate highway 25 and .75 mile north of the Bernalillo-Sandoval County line; 2,500 feet east and 2,000 feet south of the northwest corner of sec. 32, T. 12 N., R. 4 E. NAD 83, UTM 13—03 59 674 E—38 99 074 N.

A—0 to 4 inches; pale brown (10YR 6/3) gravelly fine sandy loam; brown (10YR 4/3) moist; moderate fine granular structure; slightly hard, friable, slightly sticky and nonplastic; many fine roots; 20 percent gravel; moderately alkaline; clear smooth boundary.
Bt—4 to 10 inches; brown (7.5YR 5/4) sandy clay loam, dark brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; slightly hard, friable, sticky and slightly plastic; common fine roots; common fine tubular pores; common thin clay films on faces of peds; moderately alkaline; clear wavy boundary.

Btk—10 to 20 inches; light brown (7.5YR 6/4) sandy clay loam, brown (7.5YR 5/4) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; few fine roots; common fine tubular pores; few thin clay films on faces of peds; slightly effervescent; few fine rounded calcium carbonate masses; moderately alkaline; clear wavy boundary.

Bk1—20 to 26 inches; pink (7.5YR 7/4) gravelly sandy loam, light brown (10YR 6/4) moist; massive; hard, friable, slightly sticky and slightly plastic; few fine tubular pores; 20 percent gravel; strongly effervescent; few, medium rounded calcium carbonate masses; moderately alkaline; gradual wavy boundary.

Bk2—26 to 60 inches; pink (7.5YR 7/4) very gravelly coarse sandy loam, brown (7.5YR 5/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; 50 percent gravel; slightly effervescent; few fine rounded pink calcium carbonate masses; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 30 percent clay

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 4

Bt horizon
Hue: 5YR to 10YR
Value: 4 to 6 dry, 3 to 5 moist
Chroma: 2 to 5

Bk horizon
Hue: 7.5YR or 10YR
Value: 5 to 7 dry, 4 to 6 moist
Content of rock fragments: 35 to 70 percent granite gravel

Tocal Series

Map unit: 282
Depth class: very shallow to shallow
Drainage class: well drained
Landform: interfluves on plateaus
Parent material: eolian material over residuum derived from tuff
Elevation: 7,000 to 8,000 feet (2,134 to 2,438 meters)
Slope: 3 to 8 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90days

Taxonomic class: Clayey, mixed Lithic Eutroboralfs

Typical Pedon

Tocal very fine sandy loam, in an area of mapping unit 282, Tocal very fine sandy loam, 3 to 8 percent slopes; Los Alamos County; Guaje Mountain Quadrangle; about .5 mile northwest of LASL administration building; 750 feet west and 700 feet south of the center of sec. 17, T. 19 N., R. 6 E. NAD 83, UTM 13—03 79 860 E—39 70 969 N.

A—0 to 5 inches; grayish brown (10YR 5/2) very fine sandy loam, very dark grayish brown (10YR 3/2) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine roots; many interstitial pores; neutral; abrupt smooth boundary.
Bt1—5 to 8 inches; reddish brown (5YR 5/3) clay loam, reddish brown (5YR 4/3) moist; moderate fine subangular blocky structure; hard, friable, sticky and plastic; many fine roots; few very fine interstitial pores; thin continuous clay films on faces of peds; neutral; abrupt smooth boundary.
Bt2—8 to 11 inches; reddish brown (5YR 5/3) clay, reddish brown (5YR 4/3) moist; moderate coarse prismatic structure parting to moderate medium subangular blocky; hard, friable, sticky and plastic; many medium roots; few very fine tubular pores; thick continuous clay films on faces of peds; neutral; clear smooth boundary.
2Bt3—11 to 14 inches; light brown (7.5YR 6/4) silt loam, dark brown (7.5YR 4/4) moist; massive; hard, friable, sticky and plastic; many medium roots; few very fine tubular pores; few reddish brown (5YR 4/4) clay filling in pores; neutral; abrupt smooth boundary.
2Cr—14 inches; tuff.

Range in Characteristics

Particle-size control section: 15 to 45 percent clay
Depth to tuff bedrock: 8 to 20 inches

A horizon
Hue: 7.5YR or 10YR
Value: 4 to 6 dry, 2 to 4 moist
Chroma: 2 or 3

B horizon
Hue: 7.5YR or 5YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 3 to 6

Totavi Series

Map units: 52, 88
Depth class: very deep
Drainage class: somewhat excessively drained
Landform: stream terraces, closed depressions, and valley floors
Parent material: stream alluvium derived from tuff and pumice
Elevation: 7,000 to 8,800 feet (2,134 to 2,682 meters)
Slope: 0 to 5 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Ashy, frigid Mollic Vitrandepts

Typical Pedon

Totavi loamy sand, in an area of mapping unit 52, Totavi loamy sand, 0 to 5 percent slopes; Los Alamos County; Frijoles Quadrangle; about 1.4 miles east of Meson Lab entrance; 100 feet south and 150 feet east of the center of sec. 24, T. 19 N., R. 6 E. NAD 83, UTM 13—03 86 516 E—39 69 460 N.

A—0 to 15 inches; grayish brown (10YR 5/2) loamy sand, very dark brown (10YR 2/2) moist; weak medium subangular blocky structure; soft, very friable, nonsticky and nonplastic; many very fine and fine roots; 10 percent pebble-sized tuff and pumice fragments; neutral; abrupt wavy boundary.
C1—15 to 19 inches; grayish brown (10YR 5/2) loamy sand, very dark grayish brown (10YR 3/2) moist; single grain; loose, very friable, nonsticky and nonplastic; common very fine and fine roots; about 50 percent of the fine earth fraction is medium or coarser sand; 10 percent pebble-sized tuff and pumice fragments; neutral; abrupt boundary.
C2—19 to 60 inches; grayish brown (10YR 5/2) loamy sand, very dark grayish brown (10YR 3/2) moist; weak medium subangular blocky structure; soft, very friable, nonsticky and plastic; few very fine roots; about 35 percent of the fine earth fraction is medium or coarser sand; 10 percent pebble-sized tuff and pumice fragments; neutral.

Range in Characteristics

Particle-size control section: 5 to 15 percent clay
Content of rock fragments: tuff, pumice, latite, dacite

A horizon
Hue: 7.5YR or 10YR
Value: 4 or 5 dry, 2 or 3 moist
Chroma: 2 or 3, dry or moist
Texture: loamy sand or sandy loam

C or Bw horizon
Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 4

Trail Series

Map units: 10, 11, 29, 430, 431, 830, 831
Depth class: very deep
Drainage class: moderately well drained, somewhat excessively drained
Landform: flood plains, alluvial fans, channels, and valley floor remnants
Parent material: eolian material and stream alluvium derived from sandstone
Elevation: 5,000 to 6,000 feet (1,524 to 1,829 meters)
Slope: 0 to 4 percent
Climatic data:
Mean annual precipitation: 8 to 10 inches (203 to 254 millimeters)
Mean annual air temperature: 53 to 55 degrees F. (11.7 to 12.8 degrees C.)
Frost-free period: 140 to 160 days

Taxonomic class: Sandy, mixed, mesic Typic Torrifluvents

Typical Pedon

Trail fine sandy loam, in an area of mapping unit 11, Trail fine sandy loam, 0 to 1 percent slopes; Sandoval County; Jemez Pueblo Quadrangle; Pena Blanca Area, unsectionized; NAD 83, UTM 13—03 47 611 E—39 36 023 N.

Ap—0 to 9 inches; light yellowish brown (10YR 6/4) fine sandy loam, brown (10YR 4/3) moist; massive; soft, very friable, slightly sticky and slightly plastic; common fine roots; strongly effervescent; moderately alkaline; clear smooth boundary.

C1—9 to 36 inches; very pale brown (10YR 7/4) loamy sand with stratum of sandy loam, brown (10YR 4/3) moist; massive; soft, very friable, nonsticky and nonplastic; few fine roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C2—36 to 60 inches; very pale brown (10YR 7/4) sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; strongly effervescent; strongly alkaline.

Range in Characteristics

A horizon
Hue: 2.5YR to 10YR
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 2 to 6 dry, 2, 3 or 4 moist
Texture: loamy sand, fine sandy loam, loam, or silty clay loam

C horizon
Hue: 2.5YR to 10YR
Value: 5 to 7 dry, 4 to 6 moist
Chroma: 2 to 6 dry, 2, 3 or 4 moist
Texture: loamy sand, loamy fine sand, fine sand, sand with thin strata of sandy loam, fine sandy loam, very fine sandy loam, loam, silt loam

Tranquilar Series

Map units: 302, 311
Depth class: very deep
Drainage class: somewhat poorly drained
Landform: stream terraces and valley floors
Parent material: lacustrine deposits from rhyolite and tuff
Elevation: 8,500 to 9,200 feet (2,591 to 2,804 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Very-fine, montmorillonitic, frigid Typic Argialbolls

Typical Pedon

Tranquilar silty clay loam, in an area of mapping unit 302, Tranquilar-Jarmillo complex, 1 to 8 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about 2.5 miles southeast from the northwest corner of Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 56 228 E—39 83 041 N.

A1—0 to 4 inches; dark grayish brown (10YR 4/2) silty clay loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; soft, very friable, sticky and plastic; many fine and very fine roots; slightly acid; clear smooth boundary.
A2—4 to 8 inches; dark grayish brown (10YR 4/2) silty clay loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; common very fine and few medium roots; slightly acid; clear smooth boundary.
E1—8 to 11 inches; gray (10YR 6/1) silty clay loam, very dark grayish brown (10YR 3/2) moist; weak fine subangular blocky structure; slightly hard, friable, sticky and plastic; few very fine roots; slightly acid; abrupt smooth boundary.

E2—11 to 13 inches; light gray (10YR 7/2) ped exteriors silty clay loam, dark grayish brown (10YR 4/2) moist; ped interiors, light brownish gray (10YR 6/2), very dark grayish brown (10YR 3/2) moist; few fine faint reddish yellow (7.5YR 6/6) mottles inside peds; weak thin platy structure; slightly hard, friable, sticky and plastic; few very fine roots; medium acid; abrupt smooth boundary.

Bt1—13 to 20 inches; very dark grayish brown (10YR 3/2) ped exteriors clay, very dark brown (10YR 2/2) moist; ped interiors brown (10YR 5/3), dark brown (10YR 3/3) moist; few fine faint reddish yellow (7.5YR 6/6) mottles inside peds; strong medium prismatic structure parting to strong medium angular blocky; very hard, very firm, very sticky and very plastic; few very fine and few medium roots; thin organic films; thin clay films on faces of peds; pressure faces on a few peds; strongly acid; gradual wavy boundary.

Bt2—20 to 34 inches; dark grayish brown (10YR 4/2) ped exteriors clay, very dark grayish brown (10YR 3/2) moist; clay interiors very pale brown (10YR 7/3), brown (10YR 4/3) moist; few fine faint reddish yellow (7.5YR 6/6) mottles inside peds; strong medium angular blocky structure; very hard, very firm, very sticky and very plastic; few very fine roots; continuous moderately thick clay films and organic stains on faces of peds; pressure faces on a few peds; very strongly acid; gradual wavy boundary.

Bt3—34 to 42 inches; light yellowish brown (10YR 6/4) clay, dark yellowish brown (10YR 4/4) moist; common fine prominent yellowish red (5YR 5/6) mottles; moderate coarse prismatic structure parting to moderate fine and medium angular blocky; very hard, very firm, very sticky and very plastic; few very fine and medium roots; continuous moderately thick clay films on faces of peds with discontinuous patchy organic films; pressure faces on a few peds; very strongly acid; gradual wavy boundary.

Bt4—42 to 50 inches; light gray (2.5Y 7/2) clay, light brownish gray (2.5Y 6/2) moist; common, fine, prominent reddish yellow (7.5YR 6/6) mottles; weak coarse prismatic structure parting to moderate fine and medium angular blocky; very hard, very firm, very sticky and very plastic; few very fine and medium roots; continuous moderately thick clay films on faces of peds; pressure faces on a few peds; extremely acid; gradual wavy boundary.

Bt5—50 to 60 inches; light gray (2.5Y 7/2) clay, light brownish gray (2.5Y 6/2) moist; common fine prominent reddish yellow (7.5YR 6/8) mottles; very dark grayish brown (2.5Y 3/2) moist; moderate coarse prismatic structure parting to moderate fine and medium subangular blocky; hard, firm, sticky and plastic; few very fine and medium roots; continuous moderately thick clay films on faces of peds; very strongly acid; gradual wavy boundary.

Range in Characteristics

Particle-size control section: 60 to 75 percent clay
Depth to a seasonal water table: 20 to 48 inches from March to July

A horizon
Value: 3 to 5 dry, 2 or 3 moist
Chroma: 1 or 2 dry or moist
Texture: silt loam, silty clay loam

E horizon
Value: 5 to 7 dry, 3 to 6 moist
Chroma: 1 or 2 dry or moist
Texture: silt loam or silty clay loam

Bt horizon
Hue: 7.5YR or 10YR
Value: 3 to 7 dry, 2 to 7 moist
Chroma: 3 to 8

Tsosie Series

Map unit: 270
Depth class: very deep
Drainage class: well drained
Landform: stream terraces and alluvial fans
Parent material: stream alluvium derived from shale and sandstone
Elevation: 6,600 to 7,000 feet (2,012 to 2,134 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Fine-loamy, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

Tsosie clay loam, in an area of mapping unit 270, Blancot-Councelor-Tsosie association, 0 to 5 percent slopes; Sandoval County; Galisteo SE Quadrangle; about 8 miles south of Galisteo, 1,100 feet north and 2,200 feet west of the southeast corner of sec. 6, T. 21 N., R. 6 W. NAD 83, UTM 13—02 74 088 E—39 95 089 N.

A—0 to 2 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; weak fine granular structure; soft, very friable, slightly sticky and slightly plastic; few very fine and fine roots; few very fine and fine continuous pores; slightly effervescent; moderately alkaline; clear smooth boundary.
C1—2 to 10 inches; brown (10YR 5/3) loam, dark brown (10YR 4/3) moist; massive; hard, firm, slightly sticky and slightly plastic; common very fine roots; slightly effervescent; strongly alkaline; clear gradual boundary.
C2—10 to 20 inches; brown (10YR 5/3) clay loam, dark brown (10YR 4/3) moist; massive; very hard, very firm, sticky and plastic; few very fine roots; strongly effervescent; strongly alkaline; clear smooth boundary.
C3—20 to 26 inches; pale brown (10YR 6/3) clay loam, brown (10YR 5/3) moist; massive; hard, firm, slightly sticky and slightly plastic; few very fine roots; slightly effervescent; strongly alkaline; clear smooth boundary.
C4—26 to 36 inches; yellowish brown (10YR 5/4) clay loam, dark yellowish brown (10YR 4/4) moist; massive; hard, friable, slightly sticky and slightly plastic; few very fine roots; few very fine continuous pores; strongly alkaline; clear smooth boundary.
C5—36 to 44 inches; yellowish brown (10YR 5/4) sandy loam, dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; few very fine roots; moderately alkaline; clear smooth boundary.
C6—44 to 55 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; soft, very friable, nonsticky and nonplastic; strongly alkaline; clear smooth boundary.
C7—55 to 60 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 5/3) moist; massive; slightly hard, friable, nonsticky and nonplastic; strongly effervescent; strongly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 2.5Y or 10YR
Value: 5 to 7 dry, 4 or 5 moist
Chroma: 2 to 4

C horizon
Hue: 2.5Y or 10YR
Value: 5 to 7 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: clay loam, sandy clay loam, or loam in upper part of the subsoil; stratified sandy loam to silty clay loam in the lower part.

Note: In some pedons, fine sandy loam, sandy loam, and silt loam textures occur below the control section or as thin lenses within it.

Vastine Series

Map unit: 301
Depth class: very deep
Drainage class: poorly drained
Landform: flood plains, stream terraces, and valley floors
Parent material: mixed stream alluvium
Elevation: 8,400 to 8,600 feet (2,560 to 2,621 meters)
Slope: 0 to 3 percent
Climatic data:
Mean annual precipitation: 20 to 25 inches (508 to 635 millimeters)
Mean annual air temperature: 42 to 45 degrees F. (5.6 to 7.2 degrees C.)
Frost-free period: 60 to 90 days

Taxonomic class: Fine-loamy over sandy or sandy-skeletal, mixed, frigid Typic Haplaquolls

Typical Pedon

Vastine silt loam, in an area of mapping unit 301, Vastine-Jarola silt loams, 0 to 5 percent slopes; Sandoval County; Valle San Antonio Quadrangle; about .1 mile southwest of hot springs in San Antonio Valley, Baca Location No. 1; unsectionized; NAD 83, UTM 13—03 59 079 E—39 81 660 N.

A1—0 to 4 inches; dark gray (10YR 4/1) silt loam, black (10YR 2/1) moist; moderate medium granular structure; slightly hard, firm, sticky and plastic; many fine and very fine roots; neutral; clear smooth boundary.
A2—4 to 11 inches; gray (10YR 5/1) loam, very dark gray (10YR 3/1) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common fine and few very fine roots; neutral; gradual smooth boundary.
Bw—11 to 24 inches; light gray (10YR 6/1) loam, gray (10YR 5/1) moist; common fine distinct pale yellow (2.5Y 7/4) mottles; moderate medium blocky structure; hard, firm, sticky and plastic; few fine roots; 10 percent gravel; neutral; clear smooth boundary.
2C—24 to 60 inches; gray (10YR 5/1) very gravelly loamy sand, dark gray (10YR 4/1) moist; massive; loose, nonsticky and nonplastic; 55 percent gravel; slightly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay in the upper part of the subsoil
Depth to a seasonal high water table: 12 to 36 inches
Depth to the gravelly substratum: 24 to 33 inches

A horizon
Hue: 5Y to 7.5YR
Value: 4 or 5 dry, 2 or 3 moist
Chroma: 1 or 2

B horizon
Hue: 5Y to 7.5YR
Value: 4 to 6 dry, 2 to 5 moist
Chroma: 0 to 8.
Other features: colors in this horizon are variegated in some pedons

2C horizon
Hue: 5Y to 7.5YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 1 to 3
Content of rock fragments: 35 to 60 percent gravel is common below 24 inches
Other features: colors in this horizon are variegated in some pedons

Vessilla Series

Map units: 17, 220, 325, 342, 397, 422
Depth class: very shallow to shallow
Drainage class: well drained
Landform: structural benches on escarpments and breaks; sideslopes of hills, mesas, and ridges
Parent material: eolian material, slope alluvium, and residuum derived from sandstone
Elevation: 6,000 to 7,500 feet (1,829 to 2,286 meters)
Slope: 3 to 65 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy, mixed, calcareous, mesic Lithic Ustorthents

Typical Pedon

Vessilla gravelly fine sandy loam, in an area of mapping unit 397, Rock outcrop-Cucho-Vessilla complex, 25 to 70 percent slopes; Sandoval County; Holy Ghost Spring Quadrangle; 15 miles northwest of San Ysidro; NAD 83, UTM 13—03 28 014 E—39 50 605 N.

A—0 to 2 inches; light yellowish brown (10YR 6/4) gravelly fine sandy loam, yellowish brown (10YR 5/4) moist; weak fine granular structure; soft, very friable, slightly sticky and nonplastic; common fine and medium fine roots; 25 percent gravel; strongly effervescent; moderately alkaline; clear smooth boundary.
C—2 to 11 inches; light brown (7.5YR 6/4) gravelly fine sandy loam, brown (7.5YR 5/4) moist; massive; loose, nonsticky and nonplastic; common fine roots; 20 percent gravel; strongly effervescent; moderately alkaline; abrupt smooth boundary.
R—11 inches; sandstone.

Range in Characteristics

Particle-size control section: 12 to 20 percent clay
Depth to sandstone: 4 to 20 inches

A and C horizons
Hue: 7.5YR or 10YR
Value: 4 to 7 dry, 4 to 6 moist
Chroma: 3 to 6 dry or moist
Texture: sandy loam, fine sandy loam, loamy sand, loam, gravelly fine sandy loam, gravelly loamy sand, gravelly sandy loam, very gravelly sandy loam, gravelly loam, and channery loam

Waumac Series

Map units: 300, 307, 314, 321, 342
Depth class: very deep
Drainage class: well drained
Landform: alluvial fans, valley floors, and stream terraces
Parent material: fan and stream alluvium derived from sandstone and igneous rocks
Elevation: 5,400 to 6,900 feet (1,646 to 2,103 meters)
Slope: 1 to 20 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Coarse-loamy, mixed, calcareous, mesic Typic Ustorthents

Typical Pedon

Waumac loamy sand, in an area of mapping unit 300, Waumac-Bamac association, 1 to 7 percent slopes; Sandoval County; Santo Domingo Pueblo Quadrangle; one-half mile south of the Cochiti Indian Pueblo, 100 yards east of the Highway 85; 100 feet west and 1,070 feet north of the southeast corner of sec. 24, T. 16 N., R. 5 E. NAD 83, UTM 13—03 77 273 E—39 40 079 N.

A—0 to 3 inches; pale brown (10YR 6/3) loamy sand, dark grayish brown (10YR 4/2) moist; weak thin platy structure; soft, very friable, nonsticky and nonplastic; many very fine and common fine roots; few fine tubular pores; moderately alkaline; clear smooth boundary.
C1—3 to 31 inches; pale brown (10YR 6/3) fine sandy loam, dark yellowish brown (10YR 4/4) moist; massive; loose, nonsticky and nonplastic; few very fine roots; slightly effervescent; moderately alkaline; gradual wavy boundary.
C2—31 to 60 inches; pale brown (10YR 6/3) gravelly fine sandy loam; dark yellowish brown (10YR 4/4) moist; massive; slightly hard, friable, nonsticky and nonplastic; 20 percent gravel; slightly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay

A horizon
Hue: 7.5YR, 10YR or 2.5Y
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 to 4
Texture: loamy sand or loamy fine sand

C horizon
Hue: 5YR, 7.5YR or 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4
Texture: sandy loam, fine sandy loam, and gravelly fine sandy loam
Note: Thin strata of loamy sand and coarse sandy loam occur in some pedons. This horizon can be noncalcareous to depths of 18 inches in some pedons.

Waumac Variant Series

Map unit: 354
Depth class: shallow
Drainage class: well drained
Landform: hills
Parent material: coarse textured material derived from tuff
Elevation: 5,600 to 5,900 feet (1,707 to 1,798 meters)
Slope: 1 to 15 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (305 to 356 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10.0 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Ashy-skeletal, mesic, shallow Typic Ustorthents

Typical Pedon

Waumac Variant very gravelly sandy loam, in an area of mapping unit 354, Waumac variant very gravelly sandy loam, 1 to 15 percent slopes; Sandoval County; Cochiti Dam Quadrangle; 0.5 mile south of the old sawmill, 2,200 feet north and 1,000 feet east of the southwest corner of sec. 31, T. 17 N., R. 6 E. NAD 83, UTM 13—03 77 535 E—39 46 752 N.

A—0 to 3 inches; light brownish gray (10YR 6/2) very gravelly sandy loam, dark yellowish brown (10YR 3/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; common very fine roots; common interstitial pores; 55 percent gravel; slightly alkaline; clear smooth boundary.
C—3 to 12 inches; light brownish gray (10YR 6/2) very gravelly sandy loam, dark yellowish brown (10YR 3/4) moist; massive; slightly hard, very friable, nonsticky and nonplastic; common very fine roots; common interstitial pores; 55 percent gravel; slightly alkaline.
Cr—12 inches; tuff.

Range in Characteristics

Particle-size control section: 10 to 18 percent clay
Depth to paralithic contact: 10 to 20 inches

A horizon:
Hue: 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 2 to 4

C horizon
Hue: 10YR
Value: 5 or 6 dry, 4 or 5 moist
Chroma: 3 or 4

Wauquie Series

Map units: 348, 414, 419
Depth class: very deep
Drainage class: well drained
Landform: mountain slopes, benches, canyons, hills, and mesas
Parent material: slope alluvium and colluvium derived from granite and shale
Elevation: 6,000 to 8,400 feet (1,829 to 2,560 meters)
Slope: 8 to 55 percent
Climatic data:
Mean annual precipitation: 13 to 16 inches (330 to 406 millimeters)
Mean annual air temperature: 48 to 52 degrees F. (10 to 11.1 degrees C.)
Frost-free period: 110 to 130 days

Taxonomic class: Loamy-skeletal, mixed, mesic Aridic Haplustalfs

Typical Pedon

Wauquie extremely cobbly fine sandy loam, in an area of mapping unit 419; Santa Fe-Wauquie-Rock outcrop, 25 to 70 percent slopes; Sandoval County; La Ventana Quadrangle; about 5 miles east of La Ventana; unsectionized; NAD 83, UTM 13—03 28 986 E—39 62 292 N.

A—0 to 4 inches; reddish brown (5YR 5/4) extremely cobbly fine sandy loam, dark reddish brown (5YR 3/4) moist; moderate fine granular structure; soft, very friable, nonsticky and nonplastic; many very fine and common medium roots; many very fine vesicular pores; 5 percent stones; 25 percent cobbles, and 45 percent gravel; neutral; clear smooth boundary.

Bt1—4 to 11 inches; reddish brown (2.5YR 4/4) extremely cobbly sandy clay loam, dark reddish brown (2.5YR 3/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; many very fine and common medium roots; common very fine tubular pores; common distinct clay films on faces of peds and in pores; 5 percent stones, 25 percent cobbles and 45 percent gravel; neutral; gradual smooth boundary.

Bt2—11 to 18 inches; reddish brown (2.5YR 4/4) extremely cobbly sandy clay loam, dark reddish brown (2.5YR 3/4) moist; moderate medium subangular blocky structure; slightly hard, friable, slightly sticky and slightly plastic; common medium roots; common very fine tubular pores; common distinct clay films on faces of peds and in pores; 5 percent stones, 25 percent cobbles and 45 percent gravel; neutral; gradual smooth boundary.

Bt3—18 to 29 inches; reddish brown (5YR 4/4) extremely cobbly sandy loam, dark reddish brown (5YR 3/4) moist; massive; soft, friable, nonsticky and nonplastic; common medium roots; few very fine tubular pores; many colloidal stains on sand grains and gravel; 5 percent stones, 25 percent cobbles and 50 percent gravel; slightly alkaline; gradual smooth boundary.

Bk—29 to 60 inches; light reddish brown (5YR 6/4) extremely cobbly sand, reddish brown (5YR 5/4) moist; massive; loose, nonsticky and nonplastic; few medium roots; few interstitial pores; 5 percent stones, 25 percent cobbles, and 50 percent gravel; few calcium carbonate coatings on underside of gravel; slightly alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 5YR to 10YR
Value: 3 to 6 dry, 2 to 4 moist
Chroma: 2 to 4
Texture: extremely gravelly sandy clay loam, extremely cobbly fine sandy loam, or very gravelly fine sandy loam

Bt horizon (Btk horizon in some pedons)
Hue: 2.5YR to 10YR
Value: 4 to 6 dry, 3 or 4 moist
Chroma: 2 to 6
Texture: very gravelly clay loam, extremely cobbly sandy clay loam, very gravelly sandy clay loam, and extremely cobbly sandy loam

Bk horizon
Hue: 2.5YR to 10YR
Value: 5 to 8 dry, 4 to 6 moist
Chroma: 2 to 6
Texture: very gravelly sandy loam, very gravelly loamy coarse sand, extremely gravelly loamy sand, extremely cobbly sandy loam, extremely cobbly sand, extremely cobbly loam

Winona Series

Map unit: 228
Depth class: shallow
Drainage class: well drained
Landform: hills and plateaus
Parent material: material derived from travertine
Elevation: 5,900 to 6,300 feet (1,798 to 1,920 meters)
Slope: 8 to 25 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Loamy-skeletal, carbonatic, mesic Lithic Ustollic Calciorthids

Typical Pedon

Winona very channery fine sandy loam, in an area of mapping unit 228, Winona very channery fine sandy loam, 8 to 25 percent slopes; Sandoval County; San Ysidro Quadrangle; about 10 miles northwest of San Ysidro; NAD 83, UTM 13—03 30 477 E—39 42 612 N.

A—0 to 2 inches; brown (7.5YR 5/4) very channery fine sandy loam, dark brown (7.5YR 4/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many very fine roots; 15 percent cobbles and 40 percent channers; coarse fragments are carbonate concretions and travertine fragments coated with pendants of calcium carbonate; violently effervescent; slightly alkaline; clear smooth boundary.
Bk—2 to 13 inches; brown (7.5YR 5/4) very channery loam, dark brown (7.5YR 4/4) moist; weak fine subangular blocky structure; soft, friable, slightly sticky and slightly plastic; common very fine roots; common very fine tubular pores; 45 percent channers with calcium carbonate pendants; violently effervescent; slightly alkaline.
R—13 inches; travertine.

Range in Characteristics

Particle-size control section: 15 to 30 percent clay
Depth to bedrock: 11 to 20 inches

A horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4, 5, or 6 dry, 3 or 4 moist
Chroma: 2, 3, or 4 dry

Bk horizon
Hue: 5YR, 7.5YR, 10YR
Value: 5, 6, or 7 dry; 3, 4, 5, or 6 moist
Chroma: 2, 3, or 4, dry or moist

Witt Series

Map units: 34, 53, 217
Depth class: very deep
Drainage class: well drained
Landform: bajadas, fan terraces, and mesas
Parent material: Eolian material and fan alluvium from basalt
Elevation: 5,200 to 6,700 feet (1,585 to 2,042 meters)
Slope: 1 to 8 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Fine-silty, mixed, mesic Ustollic Haplargids

Typical Pedon

Witt loam, in an area of mapping unit 53, Witt-Harvey association, 1 to 7 percent slopes; Sandoval County; Golden Quadrangle; about 3 miles northwest of Golden; 300 feet south and 900 feet west of the northeast corner of sec. 1, T. 12 N., R. 6 E. NAD 83, UTM 13—03 86 526 E—39 07 226 N.

A—0 to 3 inches; brown (7.5YR 5/4) loam, brown (7.5YR 4/4) moist; weak fine granular structure; soft, very friable, nonsticky and nonplastic; many fine and medium roots; moderately alkaline; abrupt smooth boundary.
BA—3 to 6 inches; brown (7.5YR 4/4) silt loam, brown (7.5YR 4/4) moist; weak fine subangular blocky structure; hard, very friable, slightly sticky and slightly plastic; common fine and medium roots; mildly alkaline; clear smooth boundary.
Bt1—6 to 11 inches; brown (7.5YR 4/4) silty clay loam, brown (7.5YR 4/4) moist; moderate fine subangular blocky structure; hard, friable, slightly sticky and plastic; common fine and very fine roots; few thin clay films on faces of peds; strongly effervescent; mildly alkaline; clear smooth boundary.
Bt2—11 to 18 inches; light brown (7.5YR 6/4) silty clay loam, brown (7.5YR 4/4) moist; moderate fine and medium subangular blocky structure; hard, firm, sticky and plastic; common fine and very fine roots; few thin clay films on faces of peds; strongly effervescent; moderately alkaline; clear smooth boundary.
Btk—18 to 25 inches; light brown (7.5YR 6/4) silty clay loam, brown (7.5YR 4/4) moist; moderate medium subangular blocky structure; hard, firm, sticky and plastic; common fine and very fine roots; few thin clay films on faces of peds; strongly effervescent; common medium masses of calcium carbonate; moderately alkaline; clear smooth boundary.

Bk1—25 to 39 inches; light brown (7.5YR 6/4) silt loam, brown (7.5YR 4/4) moist; weak medium and fine subangular blocky structure; slightly hard, friable, sticky and plastic; many fine and very fine roots; strongly effervescent; common medium masses of calcium carbonate; moderately alkaline; abrupt smooth boundary.
Bk2—39 to 53 inches; pinkish white (7.5YR 8/2) silt loam, pinkish gray (7.5YR 7/2) moist; massive; slightly hard, firm, sticky and plastic; few very fine roots; violently effervescent; many medium masses of calcium carbonate; moderately alkaline; gradual wavy boundary.
C—53 to 60 inches; pink (7.5YR 7/4) silt loam, brown (7.5YR 5/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; few very fine roots; violently effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 18 to 35 percent clay

A horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 4
Texture: very fine sandy loam or loam

Bt horizon
Hue: 5YR, 7.5YR, 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 6
Texture: silty clay loam, silt loam, and loam

Bk horizon
Hue: 5YR or 7.5YR
Value: 5 to 8 dry, 4 to 7 moist
Chroma: 2 to 4
Texture: loam, silt loam, silty clay loam, or very fine sandy loam

Note: A C horizon is present in some pedons.

Zia Series

Map units: 66, 91, 93, 111, 114, 190, 207, 211, 234, 410
Depth class: very deep
Drainage class: somewhat excessively well drained
Landform: alluvial fans, stream terraces, summits of mesas and plateaus
Parent material: eolian material and fan and stream alluvium derived from sandstone
Elevation: 5,000 to 6,900 feet (1,524 to 2,103 meters)
Slope: 0 to 25 percent
Climatic data:
Mean annual precipitation: 10 to 13 inches (254 to 330 millimeters)
Mean annual air temperature: 52 to 54 degrees F. (11.1 to 12.2 degrees C.)
Frost-free period: 120 to 140 days

Taxonomic class: Coarse-loamy, mixed, calcareous, mesic Ustic Torriorthents

Typical Pedon

Zia sandy loam, in an area of mapping unit 211, Zia-Clovis association, 2 to 10 percent slopes; Sandoval County; Arroyo de las Calabacillas Quadrangle; about 6

miles east of Alamo Ranch Headquarters; 1,400 feet west and 300 feet north of the southeast corner of sec. 21, T. 13 N., R. 1 E. NAD 83, UTM 13—03 33 005 E—39 11 510 N.

A—0 to 5 inches; pale brown (10YR 6/3) sandy loam, dark brown (10YR 3/3) moist; weak medium granular structure; soft, friable, slightly sticky and slightly plastic; common very fine and few fine roots; 5 percent gravel; slightly effervescent; slightly alkaline; clear smooth boundary.

Bw—5 to 14 inches; pale brown (10YR 6/3) sandy loam, brown (10YR 4/3) moist; weak fine subangular blocky structure; soft, friable, slightly sticky and slightly plastic; few fine and very fine roots; strongly effervescent; slightly alkaline; clear smooth boundary.

C1—14 to 33 inches; light gray (10YR 7/2) sandy loam, brown (10YR 5/3) moist; massive; hard, friable, slightly sticky and slightly plastic; few fine and very fine roots; strongly effervescent; slightly alkaline; gradual smooth boundary.

C2—33 to 46 inches; very pale brown (10YR 7/3) sandy clay loam, yellowish brown (10YR 5/4) moist; massive; hard, firm, sticky and plastic; few fine and very fine roots; 5 percent gravel; violently effervescent; calcium carbonate as very few fine irregular masses; moderately alkaline; clear smooth boundary.

C3—46 to 60 inches; light yellowish brown (10YR 6/4) sandy loam, brown (10YR 5/3) moist; massive; soft, friable, slightly sticky and slightly plastic; 10 percent gravel; strongly effervescent; moderately alkaline.

Range in Characteristics

Particle-size control section: 8 to 18 percent clay

A horizon

Hue: 5YR to 10YR
Value: 4 to 7 dry, 3 to 5 moist
Chroma: 2 to 6
Texture: loamy sand, sandy loam, fine sandy loam, or loam

Bw or C horizon

Hue: 5YR to 10YR
Value: 4 to 8 dry, 3 to 7 moist
Chroma: 2 to 6
Texture: fine sandy loam or sandy loam. The C horizon contains strata of loamy sand or sandy clay loam in most pedons.

Factors of Soil Formation

Soil is a collection of natural bodies occurring on the earth's surface and is capable of supporting plants. Its properties result from the extent to which physical, chemical, and biological processes have affected the material from which soil is derived, the parent material. The main processes active in the soils of the Sandoval County area are: weathering of soil particles and rock material through dissolution and disintegration; accumulation and oxidation of organic matter in surface layers; formation of soil structure and surface crusting; movement of dissolved soil constituents with soil water, and precipitation of soil constituents from soil water; and movement of clay particles with soil water downward through the soil.

Most of these soil processes enhance plant growth, and some bring about hindrances to plant growth. Some soil processes are dependent upon other processes having reached a certain stage. Soil processes, or their lack, give the present soil its characteristics and are governed by five soil-forming factors: *time, parent material, climate, relief*, and *living organisms*. Understanding and recognizing soil-forming processes that occur affords the soil user the ability to predict the capability of soils for many uses.

Climate

The *climate* of an area is greatly responsible for the types of soil processes and for the rate at which these processes occur. The main features of climate affecting soil processes are precipitation and temperature.

The climate of the Sandoval County area at present is semi-arid continental. The lowest areas have annual precipitation of about eight inches and mean annual air temperature of about 55 degrees. These being the driest are areas of least vegetation. The small amount of organic matter produced by the vegetation is rapidly oxidized, resulting in soils with light colored surface horizons as in Sheppard and Grieta series.

With increased temperature, chemical and biochemical reactions are hastened. In addition, freeze-thaw cycles speed the weathering of soil and rock particles. The temperature also greatly affects evaporation of water from the soil and transpiration of water from plants.

As the amount of precipitation increases, the potential amount of vegetation on a soil increases. The number of days per year that the soil is moist during the frost-free period determines how much vegetation can be supported and the time during which soil processes occur. The depth to which water penetrates the soil is also very important as it determines the maximum depth of root penetration and the depth beyond which soil transforming processes are greatly slowed. If there is not enough precipitation for water to move through the entire soil and enter the ground water system, calcium carbonate deposits are precipitated at the depth of maximum water penetration.

In the cold, wet, mountainous areas of the Sandoval County area, soils such as Redondo and Calaveras series support stands of large trees. These areas receive 25 or more inches of precipitation per year and the average annual air temperature is about 40 degrees F. The soils in these areas are moist more days per year than most

other soils in the Sandoval County area. The cooler temperatures allow for a buildup of organic matter in the surface layers of these soils.

Older soils in the area have been influenced by past climates. Past climates were similar to the present one, but slightly more moist and cooler. Similar soil processes took place, at an accelerated rate when compared to present conditions. For this reason, some soils in the driest part of the Sandoval County area have strongly developed features such as the petrocalcic horizon of the Pastura series, and the calcic and argillic horizons of the Clovis series.

Living Organisms

The life associated with a soil greatly influences the processes within, the features and the characteristics of a soil.

The vegetation supported by a soil is part of this life. Plant roots provide channels for water flow into depths of soils which otherwise might receive little water. Plant material provides the bulk of the organic portion of soil that is important to fertility. Plant life is very important in retaining soils in place, protecting them from erosion. A good plant cover will reduce evaporation of water from the soil surface and reduce runoff, providing a soil with more moist days each year. The plant cover also shades the soil surface and causes the soil to stay cooler than areas exposed to direct sunlight.

Soil insects, worms, and rodents affect aeration and intake rate by mixing and burrowing. Some animals affect the vegetation on the soil by their eating habits. Large animals, especially in dry areas where soil crusts form, enhance seed germination by walking across the soil surface, providing in their hoof prints a favorable seedbed.

Microscopic organisms function importantly in nutrient cycling. Fungi, bacteria, nematodes, and others process organic material and release nutrients for further plant growth. They also add acids, gases, and other chemical compounds that affect soil processes.

Many soils have been changed as a result of human intervention. People change vegetation on soils, animal and microbial life of soils, soil climate, and relief, through urban development, farming, ranching, logging, and sundry enterprises.

Topography

Soil *topography* has a profound influence on the development of soil features. Its many facets, including degree of slope, direction of slope, shape and roughness of slope, influence the climate of a soil and the extent of erosive forces affecting a soil.

On steep soils, erosion potential is greatest and soil features develop slowly. As organic matter accumulations and weathered soil material washes away, new soil parent material or bedrock nears the surface. If the erosion is moderate or severe, it is accompanied by a decrease in vegetation and an increase in runoff water, which in turn enhances the erosion.

Soils on very slight or level slopes often receive depositions of soil material. This process also slows the development of soil features, since soil material is buried too deeply before soil transforming processes are able to cause features to develop. This process is accompanied by an increase in amount of vegetation since along with new material, the soil receives run-on water.

The climate of a soil is affected greatly by the runoff or run-on water it sheds or receives.

Soils with a concave slope such as San Mateo or Sparank series receive a great amount of their moisture from adjacent, steeper slopes. Soils with more slope shed various amounts of water, depending on their steepness, amount of vegetation, and surface roughness. Soils with a very gravelly surface composed of angular pebbles

protruding from the surface can retain precipitation, even with a steep slope. A very gravelly surface of rounded, imbedded gravel however will shed water rapidly and deprive the soil of moisture.

On steep slopes there is a wide difference in climate between adjacent north-facing and south-facing slopes. Less direct sunlight on north-facing slopes results in an evapotranspiration rate and temperatures lower than that on south-facing slopes. This accounts for more days during which the soil is moist and more vegetation on north-facing slopes.

Topography has been an important factor in developing the landforms of this area. The following are landforms recognized in the survey area and some of the soils associated with them. Landforms are not static; they are continually being created and eroded.

Alluvial Fans

Alluvial fans originate from upslope landscapes. Sediment loads are deposited when slope gradients change from upland positions to less sloping landforms. An inherent feature of fan development is the continuously changing pattern of channels and loci of deposition. Over a long period of time, these changes ensure the maintenance of fans formed by distributing material widely over the surface. The soils on this landscape position are generally very deep with soil textures highly variable depending on the local geology from which they are formed. In this survey, the soil series found on alluvial fan positions are the Querencia series.

Dunes

This landform has developed from Holocene-age and present-day eolian sands. These relatively small transverse dunes formed perpendicular to the prevailing winds. Most dunes in this area are stable due to the establishment of vegetation that restricts their activity. *Dunes* can be found as a component on most of the other landforms portrayed in this section. These soils can be very deep and located in large dune fields or as a shallow mantle over bedrock controlled surfaces. The Mespun series is found on dunes.

Escarpments

Escarpments are a familiar feature in the survey area. They are relatively steep slopes or cliffs produced by erosion and faulting. Due to the steep slopes the soils formed on this landform are generally shallow. Examples of soil series on escarpments are the Skyvillage and Santa Fe series.

Fan Remnants

On this position, soils exhibit different degrees of pedogenic (soil) development. The degree of development depends upon the amounts of translocated calcium carbonate and/or silicified clays, which are related to the age of the soil.

Fan remnants have been dissected or downcut to the point at which flooding rarely occurs. This landform has two important components. One is the summit, where erosional activity is relatively low. This area will show the different degrees of soil development and age. The second component is the side slope, where erosional activity is cutting uphill into the more stable summit. In most areas in the survey, the surface has a thick eolian mantle that is being eroded.

Soils on fan remnants vary greatly in their makeup. The Pinitos series can be found in the survey area on fan remnants.

Flood Plains

This landform is formed by early Holocene-age to present-day stream alluvium. In this survey area, floodwaters flow at low to very low gradients along valley floors and

are elongated in nature. The soils on these flood plains receive periodic depositions of fresh alluvium, causing an irregular decrease in organic carbon and weak to no soil development. Soils on this landform are predominantly very deep with soil textures highly variable depending on the local geology they are formed from. The Jocity and Trail soils are formed in flood plains found along the Rio Grande and Jemez Rivers.

Mesas and Cuestas

These landforms have two important components. The first consists of the mesa summit and the cuesta dipslope. They are both nearly level to gently sloping, bedrock-controlled surfaces that are generally stable. The Bond and Hagerman series are found on these surfaces. The soils are characterized by well-developed argillic horizons.

The second component is the escarpment, where erosional activity is cutting back into the more stable summit. Soils on this component have little or no horizon development due to the steep slopes where erosional activity is greatest. Typical soils representing this escarpment component are the Vessilla and Skyvillage series.

Mesas differ from cuestas in that an escarpment on all sides terminates the mesa summit, while a cuesta will generally have one or more sides that grade into the surrounding terrain following gentle slopes.

Stream Terraces

This position is the erosional remnant of the active flood plains that existed during the late Pleistocene to Holocene ages. The slopes are in the same general direction as the current flood plain. The soils in this position are underlain by stratified sand, gravel, loamy, silty, or clayey sediments and, in some cases, buried paleosols.

The soils on stream terraces have been stable for a sufficient time period to form cambic horizons. Formation of soil structure and accumulations of calcium carbonate and sometimes gypsum characterize a cambic horizon. This position is still subject to some flooding during major events. These rare flooding occurrences and the thin alluvial deposits from the floodwaters do not inhibit soil development. Typical soils that represent stream terraces are the Zia and Councelor series.

Mountains

The mountain slopes consist of multiple landforms and positions and may be formed by several processes are therefore not considered a geomorphic surface. Soil development on these landforms is highly dependent on the nature of the bedrock such as its chemical composition, grain size, and hardness. The most influential soil-forming factors in determining how soil developed on hills and mountains are time and the slope gradient of the bedrock.

Soils on this landform vary greatly in horizon development, from soils with no development to soils with well-developed argillic horizons. Soils that have little or no horizon development are usually found on the steeper slopes where erosional activity is greatest. Soils that have well-developed horizons are generally on gently sloping to moderately steep slopes where erosion is slight to moderate. The Redondo and Palon series are examples of soils found in the Jemez Mountains.

The interaction of all the facets of soil topography can account for wide soil variations over short distances.

Parent Material

A complex geologic history, ranging from formation of sedimentary rocks while great seas covered the earth, to volcanism and mountain forming processes provided a great many rock formations in the Sandoval County area, the constituents of which to a great extent, determined the chemical, mineralogical, and textural attributes of

the soils. Unless already unconsolidated, it is the decomposition and disintegration of these rocks which give rise to the *parent material* of soil.

Parent materials in the Sandoval County area fall into two broad categories. The first is material that, after weathering from rock, is not moved, but remains in place and is subject to soil-forming processes. The second category is unconsolidated rock-derived material that has been transported by water, wind, or by force of gravity.

Soils formed in non-transported materials have mineralogical, chemical and textural traits, which are directly related to the rock from which the material is derived. There are many examples of such soils in the Sandoval County area. The Bond, Hagerman, Skyvillage, Vessilla, and Sedgran series all contain high amounts of sand-sized quartz, inherited from their weathered sandstone parent material. Soils developed from weathered shale, such as Menefee, Sandoval, Camino, and Cucho series contain a great deal of silt- and clay-sized particles of various clay minerals, feldspars, and some quartz. Other soils formed in place from weathered rock material include the Sedgran and Osha series from weathered granite, the Redondo series from weathered tuff, and the Deama series from weathered limestone.

Soils formed in transported materials can have particles weathered from one rock type, a few or many types, depending on the method and distance of transport. *Colluvial* soils are formed in material moved by the force of gravity, which is transported a relatively short distance, down slopes. The Wauquie series formed in material moved down slopes after weathering from granite and shale. Alanos series formed in transported weathered tuff, and Palon series are formed in weathered rhyolite that has moved down slopes.

The second type of transported soil parent material is *eolian*, or wind blown sediments. These are materials that begin as particles on the surface of other soils, and end up comprising the entire depth of a new soil. The Pinavetes, Sheppard, and Royosa series, when found in upland areas, are derived from eolian sand.

Alluvium is the third type of transported soil parent material found in the Sandoval County area. It is material that has been moved and deposited by streams and rivers. Alluvium is rarely derived from one rock type, and its sediments generally are of diverse mineralogy diversified. Often alluvial sediments are sorted according to texture. It is deposited in layers, which are often well defined and contrasting in texture, color, and organic matter content. Alluvium is found throughout the Sandoval County area and its age varies greatly. Recent deposits of alluvium are found along the Rio Grande, Rio Puerco and their tributaries. Soils such as the Gilco, Aga, San Mateo, Peralta, Sparank, Jocity, and Sparham series are formed in recent alluvium and display well defined layering. Older alluvium, much of which was deposited by the ancestral Rio Grande and its tributaries is locally extensive in the survey area. Soil development processes have obliterated most evidence of layering in these soils. Some soils formed in old alluvium are Sheppard, Bamac, Espiritu, Cascajo, and Grieta series.

Many soils in the Sandoval County area are formed in more than one kind of parent material. Mountain soils, such as Laventana series, are often formed in a mantle of colluvium overlying in situ material weathered from bedrock. Soils atop basalt mesas, like Prieta series formed in in situ weathered basalt material mixed with eolian silt. Fragua series formed in eolian sands mixed with weathered sandstone, and sometimes have a cap of colluvial basalt particles. All soils in the area receive eolian deposits, in varying amounts. Often this is in minor yearly contributions of calcareous dust, which over many years can bring about a highly calcareous soil.

In addition to being the initial material on which soil processes act, the parent material partly affects which and how fast soil-transforming processes occur. This is affected mainly by the rate that the parent material weathers, its mineralogy and the particle size of its weathering products.

Time

The formation of parent material (the unconsolidated mineral and organic material which when exposed at the earth's surface give rise to soil) by the weathering of geologic deposits requires a great amount of *time*. In addition, soil processes require a period of time before bringing about soil properties significantly different from properties inherited from the parent material. Many soil processes are dependent on the previous operation of other, different soil processes.

Therefore, the amount of time that a soil has been in place is very important to its present character. In the Sandoval County area, soils in the Rio Grande and Rio Puerco valleys have been there a short time, resulting in soils like Gilco, Aga, Jocity, and Sparank series that have little evidence of operating soil processes except for the accumulation of a small amount of organic matter in the surface layer. These and other young soils resemble very closely the original parent material from which they were derived.

Older soils have developed features, such as argillic horizons, calcic horizons, cambic horizons, which indicate the relative length of time a soil has been in place, and which processes have been operational in the soil. The older a soil becomes, the less it resembles the parent material from which it was derived.

Recognition of horizons and features, with knowledge of how their accompanying processes affect soil fertility, soil bulk density and other properties give great insight into the value of soil for specific uses. All of the five soil-forming factors occur in wide variation throughout the Sandoval County area, resulting in a great variety of soils. These soils represent a great natural resource and provide for a multiplicity of land uses. Knowledge of soils and their formation can help the user to protect and use the resources wisely.

Glossary

ABC soil. A soil having an A, a B, and a C horizon.

AC soil. A soil having only an A and a C horizon. Commonly, such soil formed in recent alluvium or on steep, rocky slopes.

Aeration, soil. The exchange of air in soil with air from the atmosphere. The air in a well aerated soil is similar to that in the atmosphere; the air in a poorly aerated soil is considerably higher in carbon dioxide and lower in oxygen.

Aggregate, soil. Many fine particles held in a single mass or cluster. Natural soil aggregates, such as granules, blocks, or prisms, are called peds. Clods are aggregates produced by tillage or logging.

Alkali (sodic) soil. A soil having so high a degree of alkalinity (pH 8.5 or higher) or so high a percentage of exchangeable sodium (15 percent or more of the total exchangeable bases), or both, that plant growth is restricted.

Alluvial cone. The material washed down the sides of mountains and hills by ephemeral streams and deposited at the mouth of gorges in the form of a moderately steep, conical mass descending equally in all directions from the point of issue.

Alluvial fan. The fanlike deposit of a stream where it issues from a gorge upon a plain or of a tributary stream near or at its junction with its main stream.

Alluvium. Material, such as sand, silt, or clay, deposited on land by streams.

Animal unit month (AUM). The amount of forage required by one mature cow of approximately 1,000 pounds weight, with or without a calf, for 1 month.

Aquic conditions. Current soil wetness characterized by saturation, reduction, and redoximorphic features.

Argillic horizon. A subsoil horizon characterized by an accumulation of illuvial clay.

Arroyo. The flat-floored channel of an ephemeral stream, commonly with very steep to vertical banks cut in alluvium.

Aspect. The direction in which a slope faces.

Association, soil. A group of soils or miscellaneous areas geographically associated in a characteristic repeating pattern and defined and delineated as a single map unit.

Available water capacity (available moisture capacity). The capacity of soils to hold water available for use by most plants. It is commonly defined as the difference between the amount of soil water at field moisture capacity and the amount at wilting point. It is commonly expressed as inches of water per inch of soil. The capacity, in inches, in a 60-inch profile or to a limiting layer is expressed as:

Very low	0 to 3
Low	3 to 6
Moderate	6 to 9
High	9 to 12
Very high	more than 12

Backslope. The position that forms the steepest and generally linear, middle portion of a hillslope. In profile, backslopes are commonly bounded by a convex shoulder above and a concave footslope below.

Badland. Steep or very steep, commonly nonstony, barren land dissected by many intermittent drainage channels. Badland is most common in semiarid and arid regions where streams are entrenched in soft geologic material. Local relief generally ranges from 25 to 500 feet. Runoff potential is very high, and geologic erosion is active.

Bajada. A broad alluvial slope extending from the base of a mountain range out into a basin and formed by coalescence of separate alluvial fans.

Base saturation. The degree to which material having cation-exchange properties is saturated with exchangeable bases (sum of Ca, Mg, Na, and K), expressed as a percentage of the total cation-exchange capacity.

Base slope. A geomorphic component of hills consisting of the concave to linear (perpendicular to the contour) slope that, regardless of the lateral shape, forms an apron or wedge at the bottom of a hillside dominated by colluvium and slope-wash sediments (for example, slope alluvium).

Bedding planes. Fine strata, less than 5 millimeters thick, in unconsolidated alluvial, eolian, lacustrine, or marine sediment.

Bedrock. The solid rock that underlies the soil and other unconsolidated material or that is exposed at the surface.

Bedrock-controlled topography. A landscape where the configuration and relief of the landforms are determined or strongly influenced by the underlying bedrock.

Bench terrace. A raised, level or nearly level strip of earth constructed on or nearly on a contour, supported by a barrier of rocks or similar material, and designed to make the soil suitable for tillage and to prevent accelerated erosion.

Blowout. A shallow depression from which all or most of the soil material has been removed by the wind. A blowout has a flat or irregular floor formed by a resistant layer or by an accumulation of pebbles or cobbles. In some blowouts the water table is exposed.

Bottom land. The normal flood plain of a stream, subject to flooding.

Boulders. Rock fragments larger than 2 feet (60 centimeters) in diameter.

Breaks. The steep and very steep broken land at the border of an upland summit that is dissected by ravines.

Brush management. Use of mechanical, chemical, or biological methods to make conditions favorable for reseeding or to reduce or eliminate competition from woody vegetation and thus allow understory grasses and forbs to recover. Brush management increases forage production and thus reduces the hazard of erosion. It can improve the habitat for some species of wildlife.

Butte. An isolated small mountain or hill with steep or precipitous sides and a top variously flat, rounded, or pointed that may be a residual mass isolated by erosion or an exposed volcanic neck.

Calcareous soil. A soil containing enough calcium carbonate (commonly combined with magnesium carbonate) to effervesce visibly when treated with cold, dilute hydrochloric acid.

Caliche. A more or less cemented deposit of calcium carbonate in soils of warm-temperate, subhumid to arid areas. Caliche occurs as soft, thin layers in the soil or as hard, thick beds directly beneath the solum, or it is exposed at the surface by erosion.

California bearing ratio (CBR). The load-supporting capacity of a soil as compared to that of standard crushed limestone, expressed as a ratio. First standardized in California. A soil having a CBR of 16 supports 16 percent of the load that would be supported by standard crushed limestone, per unit area, with the same degree of distortion.

Canopy. The leafy crown of trees or shrubs. (See “Crown.”)

Canyon. A long, deep, narrow, very steep sided valley with high, precipitous walls in an area of high local relief.

Capillary water. Water held as a film around soil particles and in tiny spaces between particles. Surface tension is the adhesive force that holds capillary water in the soil.

Catena. A sequence, or "chain," of soils on a landscape that formed in similar kinds of parent material but have different characteristics as a result of differences in relief and drainage.

Cation. An ion carrying a positive charge of electricity. The common soil cations are calcium, potassium, magnesium, sodium, and hydrogen.

Cation-exchange capacity. The total amount of exchangeable cations that can be held by the soil, expressed in terms of milliequivalents per 100 grams of soil at neutrality (pH 7.0) or at some other stated pH value. The term, as applied to soils, is synonymous with base-exchange capacity but is more precise in meaning.

Catsteps. Very small, irregular terraces on steep hillsides, especially in pasture, formed by the trampling of cattle or the slippage of saturated soil.

Cement rock. Shaly limestone used in the manufacture of cement.

Channery soil material. Soil material that has, by volume, 15 to 35 percent thin, flat fragments of sandstone, shale, slate, limestone, or schist as much as 6 inches (15 centimeters) along the longest axis. A single piece is called a "channer."

Chemical treatment. Control of unwanted vegetation through the use of chemicals.

Chiseling. Tillage with an implement having one or more soil-penetrating points that shatter or loosen hard, compacted layers to a depth below normal plow depth.

Clay. As a soil separate, the mineral soil particles less than 0.002 millimeter in diameter. As a soil textural class, soil material that is 40 percent or more clay, less than 45 percent sand, and less than 40 percent silt.

Clay depletions. Low-chroma zones having a low content of iron, manganese, and clay because of the chemical reduction of iron and manganese and the removal of iron, manganese, and clay. A type of redoximorphic depletion.

Clay film. A thin coating of oriented clay on the surface of a soil aggregate or lining pores or root channels. Synonyms: clay coating, clay skin.

Claypan. A slowly permeable soil horizon that contains much more clay than the horizons above it. A claypan is commonly hard when dry and plastic or stiff when wet.

Climax plant community. The stabilized plant community on a particular site. The plant cover reproduces itself and does not change so long as the environment remains the same.

Coarse textured soil. Sand or loamy sand.

Cobble (or cobblestone). A rounded or partly rounded fragment of rock 3 to 10 inches (7.6 to 25 centimeters) in diameter.

Cobbly soil material. Material that has 15 to 35 percent, by volume, rounded or partially rounded rock fragments 3 to 10 inches (7.6 to 25 centimeters) in diameter. Very cobbly soil material has 35 to 60 percent of these rock fragments, and extremely cobbly soil material has more than 60 percent.

COLE (coefficient of linear extensibility). See Linear extensibility.

Colluvium. Soil material or rock fragments, or both, moved by creep, slide, or local wash and deposited at the base of steep slopes.

Complex slope. Irregular or variable slope. Planning or establishing terraces, diversions, and other water-control structures on a complex slope is difficult.

Complex, soil. A map unit of two or more kinds of soil or miscellaneous areas in such an intricate pattern or so small in area that it is not practical to map them separately at the selected scale of mapping. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas.

Concretions. Cemented bodies with crude internal symmetry organized around a point, a line, or a plane. They typically take the form of concentric layers visible to the naked eye. Calcium carbonate, iron oxide, and manganese oxide are common

compounds making up concretions. If formed in place, concretions of iron oxide or manganese oxide are generally considered a type of redoximorphic concentration.

Conglomerate. A coarse grained, clastic rock composed of rounded or subangular rock fragments more than 2 millimeters in diameter. It commonly has a matrix of sand and finer textured material. Conglomerate is the consolidated equivalent of gravel.

Conservation tillage. A tillage system that does not invert the soil and that leaves a protective amount of crop residue on the surface throughout the year.

Consistence, soil. Refers to the degree of cohesion and adhesion of soil material and its resistance to deformation when ruptured. Consistence includes resistance of soil material to rupture and to penetration; plasticity, toughness, and stickiness of puddled soil material; and the manner in which the soil material behaves when subject to compression. Terms describing consistence are defined in the "Soil Survey Manual."

Control section. The part of the soil on which classification is based. The thickness varies among different kinds of soil, but for many it is that part of the soil profile between depths of 10 inches and 40 or 80 inches.

Coppice dune. A small dune of fine grained soil material stabilized around shrubs or small trees.

Corrosion. Soil-induced electrochemical or chemical action that dissolves or weakens concrete or uncoated steel.

Cover crop. A close-growing crop grown primarily to improve and protect the soil between periods of regular crop production, or a crop grown between trees and vines in orchards and vineyards.

Cropping system. Growing crops according to a planned system of rotation and management practices.

Crop residue management. Returning crop residue to the soil, which helps to maintain soil structure, organic matter content, and fertility and helps to control erosion.

Cuesta. A hill or ridge that has a gentle slope on one side and a steep slope on the other; specifically, an asymmetric, homoclinal ridge capped by resistant rock layers of slight or moderate dip.

Culmination of the mean annual increment (CMAI). The average annual increase per acre in the volume of a stand. Computed by dividing the total volume of the stand by its age. As the stand increases in age, the mean annual increment continues to increase until mortality begins to reduce the rate of increase. The point where the stand reaches its maximum annual rate of growth is called the culmination of the mean annual increment.

Deferred grazing. Postponing grazing or resting grazing land for a prescribed period.

Depth, soil. Generally, the thickness of the soil over bedrock. Very deep soils are more than 60 inches deep over bedrock; deep soils, 40 to 60 inches; moderately deep, 20 to 40 inches; shallow, 10 to 20 inches; and very shallow, less than 10 inches.

Desert pavement. On a desert surface, a layer of gravel or larger fragments that was emplaced by upward movement of the underlying sediments or that remains after finer particles have been removed by running water or the wind.

Dip slope. A slope of the land surface, roughly determined by and approximately conforming to the dip of the underlying bedrock.

Diversion (or diversion terrace). A ridge of earth, generally a terrace, built to protect downslope areas by diverting runoff from its natural course.

Drainage class (natural). Refers to the frequency and duration of wet periods under conditions similar to those under which the soil formed. Alterations of the water regime by human activities, either through drainage or irrigation, are not a

consideration unless they have significantly changed the morphology of the soil. Seven classes of natural soil drainage are recognized—*excessively drained, somewhat excessively drained, well drained, moderately well drained, somewhat poorly drained, poorly drained,* and *very poorly drained*. These classes are defined in the "Soil Survey Manual."

Drainage, surface. Runoff, or surface flow of water, from an area.

Draw. A small stream valley that generally is more open and has broader bottom land than a ravine or gulch.

Duff. A generally firm organic layer on the surface of mineral soils. It consists of fallen plant material that is in the process of decomposition and includes everything from the litter on the surface to underlying pure humus.

Ecological site. An area where climate, soil, and relief are sufficiently uniform to produce a distinct natural plant community. An ecological site is the product of all the environmental factors responsible for its development. It is typified by an association of species that differ from those on other ecological sites in kind and/or proportion of species or in total production.

Eluviation. The movement of material in true solution or colloidal suspension from one place to another within the soil. Soil horizons that have lost material through eluviation are eluvial; those that have received material are illuvial.

Endosaturation. A type of saturation of the soil in which all horizons between the upper boundary of saturation and a depth of 2 meters are saturated.

Eolian soil material. Earthy parent material accumulated through wind action; commonly refers to sandy material in dunes or to loess in blankets on the surface.

Ephemeral stream. A stream, or reach of a stream, that flows only in direct response to precipitation. It receives no long-continued supply from melting snow or other source, and its channel is above the water table at all times.

Episaturation. A type of saturation indicating a perched water table in a soil in which saturated layers are underlain by one or more unsaturated layers within 2 meters of the surface.

Erosion. The wearing away of the land surface by water, wind, ice, or other geologic agents and by such processes as gravitational creep.

Erosion (geologic). Erosion caused by geologic processes acting over long geologic periods and resulting in the wearing away of mountains and the building up of such landscape features as flood plains and coastal plains. Synonym: natural erosion.

Erosion (accelerated). Erosion much more rapid than geologic erosion, mainly as a result of human or animal activities or of a catastrophe in nature, such as a fire, that exposes the surface.

Escarpment. A relatively continuous and steep slope or cliff breaking the general continuity of more gently sloping land surfaces and resulting from erosion or faulting. Synonym: scarp.

Extrusive rock. Igneous rock derived from deep-seated molten matter (magma) emplaced on the earth's surface.

Fan remnant. A relict alluvial fan, no longer a site of active deposition, incised by younger and lower alluvial surfaces.

Fertility, soil. The quality that enables a soil to provide plant nutrients, in adequate amounts and in proper balance, for the growth of specified plants when light, moisture, temperature, tilth, and other growth factors are favorable.

Fibric soil material (peat). The least decomposed of all organic soil material. Peat contains a large amount of well preserved fiber that is readily identifiable according to botanical origin. Peat has the lowest bulk density and the highest water content at saturation of all organic soil material.

Field moisture capacity. The moisture content of a soil, expressed as a percentage of the ovendry weight, after the gravitational, or free, water has drained away; the field moisture content 2 or 3 days after a soaking rain; also called *normal field capacity, normal moisture capacity,* or *capillary capacity*.

Fine textured soil. Sandy clay, silty clay, or clay.

First bottom. The normal flood plain of a stream, subject to frequent or occasional flooding.

Flaggy soil material. Material that has, by volume, 15 to 35 percent flagstones. Very flaggy soil material has 35 to 60 percent flagstones, and extremely flaggy soil material has more than 60 percent flagstones.

Flagstone. A thin fragment of sandstone, limestone, slate, shale, or (rarely) schist 6 to 15 inches (15 to 38 centimeters) long.

Flood plain. A nearly level alluvial plain that borders a stream and is subject to flooding unless protected artificially.

Fluvial. Of or pertaining to rivers; produced by river action, as a fluvial plain.

Foothill. A steeply sloping upland that has relief of as much as 1,000 feet (300 meters) and fringes a mountain range or high-plateau escarpment.

Footslope. The position that forms the inner, gently inclined surface at the base of a hillslope. In profile, footslopes are commonly concave. A footslope is a transition zone between upslope sites of erosion and transport (shoulders and backslopes) and downslope sites of deposition (toeslopes).

Forb. Any herbaceous plant not a grass or a sedge.

Forest cover. All trees and other woody plants (underbrush) covering the ground in a forest.

Forest type. A stand of trees similar in composition and development because of given physical and biological factors by which it may be differentiated from other stands.

Genesis, soil. The mode of origin of the soil. Refers especially to the processes or soil-forming factors responsible for the formation of the solum, or true soil, from the unconsolidated parent material.

Gilgai. Commonly, a succession of microbasins and microknolls in nearly level areas or of microvalleys and microridges parallel with the slope. Typically, the microrelief of clayey soils that shrink and swell considerably with changes in moisture content.

Gleyed soil. Soil that formed under poor drainage, resulting in the reduction of iron and other elements in the profile and in gray colors.

Grassed waterway. A natural or constructed waterway, typically broad and shallow, seeded to grass as protection against erosion. Conducts surface water away from cropland.

Gravel. Rounded or angular fragments of rock as much as 3 inches (2 millimeters to 7.6 centimeters) in diameter. An individual piece is a pebble.

Gravelly soil material. Material that has 15 to 35 percent, by volume, rounded or angular rock fragments, not prominently flattened, as much as 3 inches (7.6 centimeters) in diameter.

Green manure crop (agronomy). A soil-improving crop grown to be plowed under in an early stage of maturity or soon after maturity.

Ground water. Water filling all the unblocked pores of the material below the water table.

Gully. A miniature valley with steep sides cut by running water and through which water ordinarily runs only after rainfall. The distinction between a gully and a rill is one of depth. A gully generally is an obstacle to farm machinery and is too deep to be obliterated by ordinary tillage; a rill is of lesser depth and can be smoothed over by ordinary tillage.

Hard bedrock. Bedrock that cannot be excavated except by blasting or by the use of special equipment that is not commonly used in construction.

Head slope. A geomorphic component of hills consisting of a laterally concave area of a hillside, especially at the head of a drainageway. The overland waterflow is converging.

Hemic soil material (mucky peat). Organic soil material intermediate in degree of decomposition between the less decomposed fibric material and the more decomposed sapric material.

High-residue crops. Such crops as small grain and corn used for grain. If properly managed, residue from these crops can be used to control erosion until the next crop in the rotation is established. These crops return large amounts of organic matter to the soil.

Hill. A natural elevation of the land surface, rising as much as 1,000 feet above surrounding lowlands, commonly of limited summit area and having a well defined outline; hillsides generally have slopes of more than 15 percent. The distinction between a hill and a mountain is arbitrary and is dependent on local usage.

Horizon, soil. A layer of soil, approximately parallel to the surface, having distinct characteristics produced by soil-forming processes. In the identification of soil horizons, an uppercase letter represents the major horizons. Numbers or lowercase letters that follow represent subdivisions of the major horizons. An explanation of the subdivisions is given in the "Soil Survey Manual." The major horizons of mineral soil are as follows:

O horizon.—An organic layer of fresh and decaying plant residue.
A horizon.—The mineral horizon at or near the surface in which an accumulation of humified organic matter is mixed with the mineral material. Also, a plowed surface horizon, most of which was originally part of a B horizon.
E horizon.—The mineral horizon in which the main feature is loss of silicate clay, iron, aluminum, or some combination of these.
B horizon.—The mineral horizon below an A horizon. The B horizon is in part a layer of transition from the overlying A to the underlying C horizon. The B horizon also has distinctive characteristics, such as (1) accumulation of clay, sesquioxides, humus, or a combination of these; (2) prismatic or blocky structure; (3) redder or browner colors than those in the A horizon; or (4) a combination of these.
C horizon.—The mineral horizon or layer, excluding indurated bedrock, that is little affected by soil-forming processes and does not have the properties typical of the overlying soil material. The material of a C horizon may be either like or unlike that in which the solum formed. If the material is known to differ from that in the solum, an Arabic numeral, commonly a 2, precedes the letter C.
Cr horizon.—Soft, consolidated bedrock beneath the soil.
R layer.—Consolidated bedrock beneath the soil. The bedrock commonly underlies a C horizon, but it can be directly below an A or a B horizon.

Humus. The well decomposed, more or less stable part of the organic matter in mineral soils.

Hydrologic soil groups. Refers to soils grouped according to their runoff potential. The soil properties that influence this potential are those that affect the minimum rate of water infiltration on a bare soil during periods after prolonged wetting when the soil is not frozen. These properties are depth to a seasonal high water table, the infiltration rate and permeability after prolonged wetting, and depth to a very slowly permeable layer. The slope and the kind of plant cover are not considered but are separate factors in predicting runoff.

Igneous rock. Rock formed by solidification from a molten or partially molten state. Major varieties include plutonic and volcanic rock. Examples are andesite, basalt, and granite.

Illuviation. The movement of soil material from one horizon to another in the soil profile. Generally, material is removed from an upper horizon and deposited in a lower horizon.

Impervious soil. A soil through which water, air, or roots penetrate slowly or not at all. No soil is absolutely impervious to air and water all the time.

Infiltration. The downward entry of water into the immediate surface of soil or other material, as contrasted with percolation, which is movement of water through soil layers or material.

Infiltration capacity. The maximum rate at which water can infiltrate into a soil under a given set of conditions.

Infiltration rate. The rate at which water penetrates the surface of the soil at any given instant, usually expressed in inches per hour. The rate can be limited by the infiltration capacity of the soil or the rate at which water is applied at the surface.

Intake rate. The average rate of water entering the soil under irrigation. Most soils have a fast initial rate; the rate decreases with application time. Therefore, intake rate for design purposes is not a constant but is a variable depending on the net irrigation application. The rate of water intake, in inches per hour, is expressed as follows:

Less than 0.2	very low
0.2 to 0.4	low
0.4 to 0.75	moderately low
0.75 to 1.25	moderate
1.25 to 1.75	moderately high
1.75 to 2.5	high
More than 2.5	very high

Interfluve. An elevated area between two drainageways that sheds water to those drainageways.

Intermittent stream. A stream, or reach of a stream, that flows for prolonged periods only when it receives ground-water discharge or long, continued contributions from melting snow or other surface and shallow subsurface sources.

Invaders. On range, plants that encroach into an area and grow after the climax vegetation has been reduced by grazing. Generally, plants invade following disturbance of the surface.

Iron depletions. Low-chroma zones having a low content of iron and manganese oxide because of chemical reduction and removal, but having a clay content similar to that of the adjacent matrix. A type of redoximorphic depletion.

Irrigation. Application of water to soils to assist in production of crops. Methods of irrigation are:

Basin.—Water is applied rapidly to nearly level plains surrounded by levees or dikes.

Border.—Water is applied at the upper end of a strip in which the lateral flow of water is controlled by small earth ridges called border dikes, or borders.

Controlled flooding.—Water is released at intervals from closely spaced field ditches and distributed uniformly over the field.

Corrugation.—Water is applied to small, closely spaced furrows or ditches in fields of close-growing crops or in orchards so that it flows in only one direction.

Drip (or trickle).—Water is applied slowly and under low pressure to the surface of the soil or into the soil through such applicators as emitters, porous tubing, or perforated pipe.

Furrow.—Water is applied in small ditches made by cultivation implements. Furrows are used for tree and row crops.

Sprinkler.—Water is sprayed over the soil surface through pipes or nozzles from a pressure system.

Subirrigation.—Water is applied in open ditches or tile lines until the water table is raised enough to wet the soil.

Wild flooding.—Water, released at high points, is allowed to flow onto an area without controlled distribution.

Karst (topography). The relief of an area underlain by limestone that dissolves in differing degrees, thus forming numerous depressions or small basins.

Knoll. A small, low, rounded hill rising above adjacent landforms.

K_{sat}. Saturated hydraulic conductivity. (See "Permeability.")

Lacustrine deposit. Material deposited in lake water and exposed when the water level is lowered or the elevation of the land is raised.

Landslide. The rapid downhill movement of a mass of soil and loose rock, generally when wet or saturated. The speed and distance of movement, as well as the amount of soil and rock material, vary greatly.

Leaching. The removal of soluble material from soil or other material by percolating water.

Linear extensibility. Refers to the change in length of an unconfined clod as moisture content is decreased from a moist to a dry state. Linear extensibility is used to determine the shrink-swell potential of soils. It is an expression of the volume change between the water content of the clod at $^1/_3$- or $^1/_{10}$-bar tension (33kPa or 10kPa tension) and oven dryness. Volume change is influenced by the amount and type of clay minerals in the soil. The volume change is the percent change for the whole soil. If it is expressed as a fraction, the resulting value is COLE, coefficient of linear extensibility.

Liquid limit. The moisture content at which the soil passes from a plastic to a liquid state.

Loam. Soil material that is 7 to 27 percent clay particles, 28 to 50 percent silt particles, and less than 52 percent sand particles.

Loess. Fine grained material, dominantly of silt-sized particles, deposited by wind.

Low-residue crops. Such crops as corn used for silage, peas, beans, and potatoes. Residue from these crops is not adequate to control erosion until the next crop in the rotation is established. These crops return little organic matter to the soil.

Low strength. The soil is not strong enough to support loads.

Marl. An earthy, unconsolidated deposit consisting chiefly of calcium carbonate mixed with clay in approximately equal amounts.

Masses. Concentrations of substances in the soil matrix that do not have a clearly defined boundary with the surrounding soil material and cannot be removed as a discrete unit. Common compounds making up masses are calcium carbonate, gypsum or other soluble salts, iron oxide, and manganese oxide. Masses consisting of iron oxide or manganese oxide generally are considered a type of redoximorphic concentration.

Mechanical treatment. Use of mechanical equipment for seeding, brush management, and other management practices.

Medium textured soil. Very fine sandy loam, loam, silt loam, or silt.

Mesa. A broad, nearly flat topped and commonly isolated upland mass characterized by summit widths that are more than the heights of bounding erosional scarps.

Metamorphic rock. Rock of any origin altered in mineralogical composition, chemical composition, or structure by heat, pressure, and movement. Nearly all such rocks are crystalline.

Mineral soil. Soil that is mainly mineral material and low in organic material. Its bulk density is more than that of organic soil.

Miscellaneous area. An area that has little or no natural soil and supports little or no vegetation.

Major Land Resource Area. These are geographically associated land resource units. Identification of these large areas is important in statewide agricultural planning and has value in interstate, regional, and national planning.

Moderately coarse textured soil. Coarse sandy loam, sandy loam, or fine sandy loam.

Moderately fine textured soil. Clay loam, sandy clay loam, or silty clay loam.

Mollic epipedon. A thick, dark, humus-rich surface horizon (or horizons) that has high base saturation and pedogenic soil structure. It may include the upper part of the subsoil.

Morphology, soil. The physical makeup of the soil, including the texture, structure, porosity, consistence, color, and other physical, mineral, and biological properties of the various horizons, and the thickness and arrangement of those horizons in the soil profile.

Mottling, soil. Irregular spots of different colors that vary in number and size. Descriptive terms are as follows: abundance—*few, common,* and *many;* size—*fine, medium,* and *coarse;* and contrast—*faint, distinct,* and *prominent*. The size measurements are of the diameter along the greatest dimension. *Fine* indicates less than 5 millimeters (about 0.2 inch); *medium,* from 5 to 15 millimeters (about 0.2 to 0.6 inch); and *coarse,* more than 15 millimeters (about 0.6 inch).

Mountain. A natural elevation of the land surface, rising more than 1,000 feet above surrounding lowlands, commonly of restricted summit area (relative to a plateau) and generally having steep sides. A mountain can occur as a single, isolated mass or in a group forming a chain or range.

Mudstone. Sedimentary rock formed by induration of silt and clay in approximately equal amounts.

Munsell notation. A designation of color by degrees of three simple variables—hue, value, and chroma. For example, a notation of 10YR 6/4 is a color with hue of 10YR, value of 6, and chroma of 4.

Natric horizon. A special kind of argillic horizon that contains enough exchangeable sodium to have an adverse effect on the physical condition of the subsoil.

Neutral soil. A soil having a pH value of 6.6 to 7.3. (See “Reaction, soil.”)

Nodules. Cemented bodies lacking visible internal structure. Calcium carbonate, iron oxide, and manganese oxide are common compounds making up nodules. If formed in place, nodules of iron oxide or manganese oxide are considered types of redoximorphic concentrations.

Nose slope. A geomorphic component of hills consisting of the projecting end (laterally convex area) of a hillside. The overland waterflow is predominantly divergent.

Nutrient, plant. Any element taken in by a plant essential to its growth. Plant nutrients are mainly nitrogen, phosphorus, potassium, calcium, magnesium, sulfur, iron, manganese, copper, boron, and zinc obtained from the soil and carbon, hydrogen, and oxygen obtained from the air and water.

Organic matter. Plant and animal residue in the soil in various stages of decomposition. The content of organic matter in the surface layer is described as follows:

Very low	less than 0.5 percent
Low	0.5 to 1.0 percent
Moderately low	1.0 to 2.0 percent
Moderate	2.0 to 4.0 percent
High	4.0 to 8.0 percent
Very high	more than 8.0 percent

Pan. A compact, dense layer in a soil that impedes the movement of water and the growth of roots. For example, *hardpan, fragipan, claypan, plowpan,* and *traffic pan*.

Paleosols. A soil that formed on a landscape in the past with distinctive morphological features resulting from a soil-forming environment that no longer exists at the site.

Parent material. The unconsolidated organic and mineral material in which soil forms.

Ped. An individual natural soil aggregate, such as a granule, a prism, or a block.

Pedisediment. A thin layer of alluvial material that mantles an erosion surface and has been transported to its present position from higher lying areas of the erosion surface.

Pedon. The smallest volume that can be called "a soil." A pedon is three dimensional and large enough to permit study of all horizons. Its area ranges from about 10 to 100 square feet (1 square meter to 10 square meters), depending on the variability of the soil.

Percolation. The movement of water through the soil.

Permeability. The quality of the soil that enables water or air to move downward through the profile. The rate at which a saturated soil transmits water is accepted as a measure of this quality. In soil physics, the rate is referred to as "saturated hydraulic conductivity," which is defined in the "Soil Survey Manual." In line with conventional usage in the engineering profession and with traditional usage in published soil surveys, this rate of flow continues to be expressed as "permeability." Terms describing permeability, measured in inches per hour, are as follows:

Extremely slow	0.0 to 0.01 inch
Very slow	0.01 to 0.06 inch
Slow	0.06 to 0.2 inch
Moderately slow	0.2 to 0.6 inch
Moderate	0.6 inch to 2.0 inches
Moderately rapid	2.0 to 6.0 inches
Rapid	6.0 to 20 inches
Very rapid	more than 20 inches

Phase, soil. A subdivision of a soil series based on features that affect its use and management, such as slope, stoniness, and flooding.

pH value. A numerical designation of acidity and alkalinity in soil. (See "Reaction, soil.")

Plasticity index. The numerical difference between the liquid limit and the plastic limit; the range of moisture content within which the soil remains plastic.

Plastic limit. The moisture content at which a soil changes from semisolid to plastic.

Plateau. An extensive upland mass with relatively flat summit area that is considerably elevated (more than 100 meters) above adjacent lowlands and separated from them on one or more sides by escarpments.

Playa. The generally dry and nearly level lake plain that occupies the lowest parts of closed depressional areas, such as those on intermontane basin floors. Temporary flooding occurs primarily in response to precipitation and runoff.

Plowpan. A compacted layer formed in the soil directly below the plowed layer.

Ponding. Standing water on soils in closed depressions. Unless the soils are artificially drained, the water can be removed only by percolation or evapotranspiration.

Poorly graded. Refers to a coarse grained soil or soil material consisting mainly of particles of nearly the same size. Because there is little difference in size of the particles, density can be increased only slightly by compaction.

Potential native plant community. See "Climax plant community."

Potential rooting depth (effective rooting depth). Depth to which roots could penetrate if the content of moisture in the soil were adequate. The soil has no properties restricting the penetration of roots to this depth.

Prescribed burning. Deliberately burning an area for specific management purposes, under the appropriate conditions of weather and soil moisture and at the proper time of day.

Productivity, soil. The capability of a soil for producing a specified plant or sequence of plants under specific management.

Profile, soil. A vertical section of the soil extending through all its horizons and into the parent material.

Proper grazing use. Grazing at an intensity that maintains enough cover to protect the soil and maintain or improve the quantity and quality of the desirable vegetation. This practice increases the vigor and reproduction capacity of the key plants and promotes the accumulation of litter and mulch necessary to conserve soil and water.

Rangeland. Land on which the potential natural vegetation is predominantly grasses, grasslike plants, forbs, or shrubs suitable for grazing or browsing. It includes natural grasslands, savannas, many wetlands, some deserts, tundras, and areas that support certain forb and shrub communities.

Reaction, soil. A measure of acidity or alkalinity of a soil, expressed in pH values. A soil that tests to pH 7.0 is described as precisely neutral in reaction because it is neither acid nor alkaline. The degrees of acidity or alkalinity, expressed as pH values, are:

Ultra acid	less than 3.5
Extremely acid	3.5 to 4.4
Very strongly acid	4.5 to 5.0
Strongly acid	5.1 to 5.5
Moderately acid	5.6 to 6.0
Slightly acid	6.1 to 6.5
Neutral	6.6 to 7.3
Slightly alkaline	7.4 to 7.8
Moderately alkaline	7.9 to 8.4
Strongly alkaline	8.5 to 9.0
Very strongly alkaline	9.1 and higher

Redoximorphic concentrations. Nodules, concretions, soft masses, pore linings, and other features resulting from the accumulation of iron or manganese oxide. An indication of chemical reduction and oxidation resulting from saturation.

Redoximorphic depletions. Low-chroma zones from which iron and manganese oxide or a combination of iron and manganese oxide and clay has been removed. These zones are indications of the chemical reduction of iron resulting from saturation.

Redoximorphic features. Redoximorphic concentrations, redoximorphic depletions, reduced matrices, a positive reaction to alpha,alpha-dipyridyl, and other features indicating the chemical reduction and oxidation of iron and manganese compounds resulting from saturation.

Reduced matrix. A soil matrix that has low chroma in situ because of chemically reduced iron (Fe II). The chemical reduction results from nearly continuous wetness. The matrix undergoes a change in hue or chroma within 30 minutes after exposure to air as the iron is oxidized (Fe III). A type of redoximorphic feature.

Regolith. The unconsolidated mantle of weathered rock and soil material on the earth's surface; the loose earth material above the solid rock.

Relief. The elevations or inequalities of a land surface, considered collectively.
Residuum (residual soil material). Unconsolidated, weathered or partly weathered mineral material that accumulated as consolidated rock disintegrated in place.
Rill. A steep-sided channel resulting from accelerated erosion. A rill generally is a few inches deep and not wide enough to be an obstacle to farm machinery.
Rock fragments. Rock or mineral fragments having a diameter of 2 millimeters or more; for example, pebbles, cobbles, stones, and boulders.
Root zone. The part of the soil that can be penetrated by plant roots.
Runoff. The precipitation discharged into stream channels from an area. The water that flows off the surface of the land without sinking into the soil is called surface runoff. Water that enters the soil before reaching surface streams is called ground-water runoff or seepage flow from ground water.
Saline soil. A soil containing soluble salts in an amount that impairs growth of plants. A saline soil does not contain excess exchangeable sodium.
Salinity. The degree to which a soil is affected by soluble salts. Salinity is expressed as a electrical conductivity (EC) of a saturation extract. The solution resistance is measured in mmhos/cm. The degrees of salinity and their respective ratios are:

Non saline	0-2
Very slightly saline	2-4
Slightly saline	4-8
Moderately saline	8-16
Strongly saline	>16

Sand. As a soil separate, individual rock or mineral fragments from 0.05 millimeter to 2.0 millimeters in diameter. Most sand grains consist of quartz. As a soil textural class, a soil that is 85 percent or more sand and not more than 10 percent clay.
Sandstone. Sedimentary rock containing dominantly sand-sized particles.
Sapric soil material (muck). The most highly decomposed of all organic soil material. Muck has the least amount of plant fiber, the highest bulk density, and the lowest water content at saturation of all organic soil material.
Saprolite. Unconsolidated residual material underlying the soil and grading to hard bedrock below.
Saturation. Wetness characterized by zero or positive pressure of the soil water. Under conditions of saturation, the water will flow from the soil matrix into an unlined auger hole.
Second bottom. The first terrace above the normal flood plain (or first bottom) of a river.
Sedimentary rock. Rock made up of particles deposited from suspension in water. The chief kinds of sedimentary rock are conglomerate, formed from gravel; sandstone, formed from sand; shale, formed from clay; and limestone, formed from soft masses of calcium carbonate. There are many intermediate types. Some wind-deposited sand is consolidated into sandstone.
Series, soil. A group of soils that have profiles that are almost alike, except for differences in texture of the surface layer. All the soils of a series have horizons that are similar in composition, thickness, and arrangement.
Shale. Sedimentary rock formed by the hardening of a clay deposit.
Sheet erosion. The removal of a fairly uniform layer of soil material from the land surface by the action of rainfall and surface runoff.
Shrink-Swell. Soil volume changes due to increases or decreases in moisture content. Linear extensibility is used to determine the shrink-swell potential of soils. It is an expression of the volume change between the water content of the clod at $^1/_3$- or $^1/_{10}$-bar tension (33kPa or 10kPa tension) and oven dryness. Volume change is influenced by the amount and type of clay minerals in the soil. The volume change is the percent change for the whole soil. If it is expressed as a

fraction, the resulting value is COLE, coefficient of linear extensibility. The Shrink-swell classes are defined as follows:

Class	LEP
Low	<3
Moderate	3-6
High	6-9
Very High	>9

Shoulder. The position that forms the uppermost inclined surface near the top of a hillslope. It is a transition from backslope to summit. The surface is dominantly convex in profile and erosional in origin.

Side slope. A geomorphic component of hills consisting of a laterally planar area of a hillside. The overland waterflow is predominantly parallel.

Silt. As a soil separate, individual mineral particles that range in diameter from the upper limit of clay (0.002 millimeter) to the lower limit of very fine sand (0.05 millimeter). As a soil textural class, soil that is 80 percent or more silt and less than 12 percent clay.

Siltstone. Sedimentary rock made up of dominantly silt-sized particles.

Similar soils. Soils that share limits of diagnostic criteria, behave and perform in a similar manner, and have similar conservation needs or management requirements for the major land uses in the survey area.

Sinkhole. A depression in the landscape where limestone has been dissolved.

Site index. A designation of the quality of a forest site based on the height of the dominant stand at an arbitrarily chosen age. For example, if the average height attained by dominant and codominant trees in a fully stocked stand at the age of 50 years is 75 feet, the site index is 75.

Slickensides. Polished and grooved surfaces produced by one mass sliding past another. In soils, slickensides may occur at the bases of slip surfaces on the steeper slopes; on faces of blocks, prisms, and columns; and in swelling clayey soils, where there is marked change in moisture content.

Slick spot. A small area of soil having a puddled, crusted, or smooth surface and an excess of exchangeable sodium. The soil generally is silty or clayey, is slippery when wet, and is low in productivity.

Slope. The inclination of the land surface from the horizontal. Percentage of slope is the vertical distance divided by horizontal distance, then multiplied by 100. Thus, a slope of 20 percent is a drop of 20 feet in 100 feet of horizontal distance.

Sodic (alkali) soil. A soil having so high a degree of alkalinity (pH 8.5 or higher) or so high a percentage of exchangeable sodium (15 percent or more of the total exchangeable bases), or both, that plant growth is restricted.

Sodicity. The degree to which a soil is affected by exchangeable sodium. Sodicity is expressed as a sodium adsorption ratio (SAR) of a saturation extract, or the ratio of Na^{+} to $Ca^{++} + Mg^{++}$. The degrees of sodicity and their respective ratios are:

Slight	less than 13:1
Moderate	13-30:1
Strong	more than 30:1

Sodium adsorption ratio (SAR). A measure of the amount of sodium (Na) relative to calcium (Ca) and magnesium (Mg) in the water extract from saturated soil paste. It is the ratio of the Na concentration divided by the square root of one-half of the Ca + Mg concentration.

Soft bedrock. Bedrock that can be excavated with trenching machines, backhoes, small rippers, and other equipment commonly used in construction.

Soil. A natural, three-dimensional body at the earth's surface. It is capable of supporting plants and has properties resulting from the integrated effect of

climate and living matter acting on earthy parent material, as conditioned by relief over periods of time.

Soil separates. Mineral particles less than 2 millimeters in equivalent diameter and ranging between specified size limits. The names and sizes, in millimeters, of separates recognized in the United States are as follows:

Very coarse sand	2.0 to 1.0
Coarse sand	1.0 to 0.5
Medium sand	0.5 to 0.25
Fine sand	0.25 to 0.10
Very fine sand	0.10 to 0.05
Silt	0.05 to 0.002
Clay	less than 0.002

Solum. The upper part of a soil profile, above the C horizon, in which the processes of soil formation are active. The solum in soil consists of the A, E, and B horizons. Generally, the characteristics of the material in these horizons are unlike those of the material below the solum. The living roots and plant and animal activities are largely confined to the solum.

Stone line. A concentration of coarse fragments in a soil. Generally, it is indicative of an old weathered surface. In a cross section, the line may be one fragment or more thick. It generally overlies material that weathered in place and is overlain by recent sediment of variable thickness.

Stones. Rock fragments 10 to 24 inches (25 to 60 centimeters) in diameter if rounded or 15 to 24 inches (38 to 60 centimeters) in length if flat.

Stony. Refers to a soil containing stones in numbers that interfere with or prevent tillage.

Structure, soil. The arrangement of primary soil particles into compound particles or aggregates. The principal forms of soil structure are—*platy* (laminated), *prismatic* (vertical axis of aggregates longer than horizontal), *columnar* (prisms with rounded tops), *blocky* (angular or subangular), and *granular*. *Structureless* soils are either *single grained* (each grain by itself, as in dune sand) or *massive* (the particles adhering without any regular cleavage, as in many hardpans).

Subsoil. Technically, the B horizon; roughly, the part of the solum below plow depth.

Subsoiling. Tilling a soil below normal plow depth, ordinarily to shatter a hardpan or claypan.

Substratum. The part of the soil below the solum.

Subsurface layer. Any surface soil horizon (A, E, AB, or EB) below the surface layer.

Summit. The topographically highest position of a hillslope. It has a nearly level (planar or only slightly convex) surface.

Surface layer. The soil ordinarily moved in tillage, or its equivalent in uncultivated soil, ranging in depth from 4 to 10 inches (10 to 25 centimeters). Frequently designated as the “plow layer,” or the “Ap horizon.”

Surface soil. The A, E, AB, and EB horizons, considered collectively. It includes all subdivisions of these horizons.

Talus. Fragments of rock and other soil material accumulated by gravity at the foot of cliffs or steep slopes.

Taxadjuncts. Soils that cannot be classified in a series recognized in the classification system. Such soils are named for a series they strongly resemble and are designated as taxadjuncts to that series because they differ in ways too small to be of consequence in interpreting their use and behavior. Soils are recognized as taxadjuncts only when one or more of their characteristics are slightly outside the range defined for the family of the series for which the soils are named.

Terrace (geologic). An old alluvial plain, ordinarily flat or undulating, bordering a river, a lake, or the sea.

Texture, soil. The relative proportions of sand, silt, and clay particles in a mass of soil. The basic textural classes, in order of increasing proportion of fine particles, are *sand, loamy sand, sandy loam, loam, silt loam, silt, sandy clay loam, clay loam, silty clay loam, sandy clay, silty clay,* and *clay*. The sand, loamy sand, and sandy loam classes may be further divided by specifying "coarse," "fine," or "very fine."

Tilth, soil. The physical condition of the soil as related to tillage, seedbed preparation, seedling emergence, and root penetration.

Toeslope. The position that forms the gently inclined surface at the base of a hillslope. Toeslopes in profile are commonly gentle and linear and are constructional surfaces forming the lower part of a hillslope continuum that grades to valley or closed-depression floors.

Topsoil. The upper part of the soil, which is the most favorable material for plant growth. It is ordinarily rich in organic matter and is used to topdress roadbanks, lawns, and land affected by mining.

Trace elements. Chemical elements, for example, zinc, cobalt, manganese, copper, and iron, in soils in extremely small amounts. They are essential to plant growth.

Tuff. A compacted deposit that is 50 percent or more volcanic ash and dust.

Upland. Land at a higher elevation, in general, than the alluvial plain or stream terrace; land above the lowlands along streams.

Valley fill. In glaciated regions, material deposited in stream valleys by glacial meltwater. In nonglaciated regions, alluvium deposited by heavily loaded streams.

Variegation. Refers to patterns of contrasting colors assumed to be inherited from the parent material rather than to be the result of poor drainage.

Water bars. Smooth, shallow ditches or depressional areas that are excavated at an angle across a sloping road. They are used to reduce the downward velocity of water and divert it off and away from the road surface. Water bars can easily be driven over if constructed properly.

Weathering. All physical and chemical changes produced in rocks or other deposits at or near the earth's surface by atmospheric agents. These changes result in disintegration and decomposition of the material.

Well graded. Refers to soil material consisting of coarse grained particles that are well distributed over a wide range in size or diameter. Such soil normally can be easily increased in density and bearing properties by compaction. Contrasts with poorly graded soil.

Wilting point (or permanent wilting point). The moisture content of soil, on an ovendry basis, at which a plant (specifically a sunflower) wilts so much that it does not recover when placed in a humid, dark chamber.

Windthrow. The uprooting and tipping over of trees by the wind.

Tables

Table 1.--Temperature and precipitation

* A growing degree day is a unit of heat available for plant growth. It can be calculated by adding the maximum and minimum daily temperatures, dividing the sum by 2, and subtracting the temperature below which growth is minimal for the principal crops in the area (40 degrees F.)

Table 2.--Freeze dates in spring and fall

(Recorded in the period 1971-2000 at Cuba, NM #2241)

Probability	Temperature		
	24 °F or lower	28 °F or lower	32 °F or lower
Last freezing temperature in spring:			
1 year in 10 later than--	May 31	June 18	June 29
2 years in 10 later than--	May 25	June 12	June 25
5 years in 10 later than--	May 13	June 2	June 15
First freezing temperature in fall:			
1 year in 10 earlier than--	September 19	September 14	August 30
2 years in 10 earlier than--	September 24	September 18	September 4
5 years in 10 earlier than--	October 3	September 26	September 15

Table 2.--Freeze dates in spring and fall--continued

(Recorded in the period 1971-2000 at Jemez Springs, NM #4369)

Probability	Temperature		
	24 °F or lower	28 °F or lower	32 °F or lower
1 year in 10 later than--	April 20	May 6	May 19
2 years in 10 later than--	April 15	April 30	May 15
5 years in 10 later than--	April 5	April 19	May 6
First freezing temperature in fall:			
1 year in 10 earlier than--	October 21	October 4	September 26
2 years in 10 earlier than--	October 26	October 10	October 1
5 years in 10 earlier than--	November 5	October 22	October 10

Table 2.--Freeze dates in spring and fall--continued

(Recorded in the period 1971-2000 at Torreon Navajo Mission, NM #9031)

Probability	Temperature		
	24 °F or lower	28 °F or lower	32 °F or lower
Last freezing temperature in spring:			
1 year in 10 later than--	May 13	May 19	June 4
2 years in 10 later than--	May 6	May 13	May 29
5 years in 10 later than--	April 23	May 4	May 18
First freezing temperature in fall:			
1 year in 10 earlier than--	October 8	September 28	September 20
2 years in 10 earlier than--	October 14	October 4	September 25
5 years in 10 earlier than--	October 24	October 15	October 5

Table 2.--Freeze dates in spring and fall--continued

(Recorded in the period 1971-2000 at Wolf Canyon, NM #9820)

Probability	Temperature		
	24 °F or lower	28 °F or lower	32 °F or lower
Last freezing temperature in spring:			
1 year in 10 later than--	June 14	June 28	July 10
2 years in 10 later than--	June 7	June 22	July 5
5 years in 10 later than--	May 24	June 12	June 26
First freezing temperature in fall:			
1 year in 10 earlier than--	September 13	September 5	August 15
2 years in 10 earlier than--	September 19	September 10	August 22
5 years in 10 earlier than--	September 29	September 18	September 3

Table 3.--Growing season

Table 5.--Irrigated and nonirrigated yields by map unit component

(Yields in the "N" columns are for nonirrigated areas; those in the "I" columns are for irrigated areas. Yields are those that can be expected under a high level of management. Absence of a yield indicates that the soil is not suited to the crop or the crop generally is not grown on the soil.)

Table 9A.--Camp areas, picnic areas, and playgrounds

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.01 to 1.00. The larger the value, the greater the limitation. See text for further explanation of ratings in this table.)

Table 9B.--Paths, trails, and golf fairways

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.01 to 1.00. The larger the value, the greater the limitation. See text for further explanation of ratings in this table.)

Table 12A.--Source of gravel and sand

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The ratings given for the thickest layer are for the thickest layer above and excluding the bottom layer. The numbers in the value columns range from 0.00 to 0.99. The greater the value, the greater the likelihood that the bottom layer or thickest layer of the soil is a source of sand or gravel. See text for further explanation of ratings in this table.)

Table 12B.--Source of reclamation material, roadfill, and topsoil

(The information in this table indicates the dominant soil condition but does not eliminate the need for onsite investigation. The numbers in the value columns range from 0.00 to 0.99. The smaller the value, the greater the limitation. See text for further explanation of ratings in this table.)

Table 19.--Taxonomic classification of the soils

(An asterisk in the first column indicates a taxadjunct to the series. See text for a description of those characteristics that are outside the range of the series.)

Soil name	Family or higher taxonomic class
Aga	Coarse-loamy over sandy or sandy-skeletal, mixed, calcareous, mesic Typic Torrifluvents
Alanos	Clayey-skeletal, mixed Typic Eutroboralfs
Atarque	Loamy, mixed, mesic Lithic Haplustalfs
Bamac	Sandy-skeletal, mixed, mesic Typic Ustorthents
Betonnie	Coarse-loamy, mixed, mesic Ustalfic Haplargids
Blancot	Fine-loamy, mixed, mesic Ustalfic Haplargids
Bond	Loamy, mixed, mesic Lithic Ustollic Haplargids
Cajete	Ashy-skeletal, frigid Mollic Vitrandepts
Calaveras	Loamy-skeletal, mixed, frigid Dystric Eutrochrepts
Camino	Fine, mixed, mesic Ustollic Camborthids
Carjo	Fine, mixed Mollic Eutroboralfs
Cascajo	Sandy-skeletal, mixed, mesic Ustollic Calciorthids
Charo	Fine, mixed Typic Argiborolls
Clovis	Fine-loamy, mixed, mesic Ustollic Haplargids
Cochiti	Clayey-skeletal, mixed, mesic Aridic Haplustalfs
Cosey	Loamy-skeletal, mixed Typic Paleborolls
Councelor	Coarse-loamy, mixed, calcareous, mesic Ustic Torriorthents
Cucho	Fine-silty, mixed, calcareous, mesic Typic Ustorthents
Cypher	Loamy-skeletal, mixed, frigid Lithic Ustochrepts
Deama	Loamy-skeletal, carbonatic, mesic Lithic Calciustolls
Doakum	Fine-loamy, mixed, mesic Ustalfic Haplargids
El Rancho	Fine-loamy, mixed, calcareous, mesic Ustic Torriorthents
Elpedro	Fine-silty, mixed, mesic Aridic Haplustalfs
Embudo	Coarse-loamy, mixed, mesic Typic Camborthids
Eslendo	Loamy, mixed, calcareous, mesic, shallow Ustic Torriorthents
Espiritu	Loamy-skeletal, mixed, mesic Aridic Haplustalfs
Ess	Loamy-skeletal, mixed Argic Cryoborolls
Flugle	Fine-loamy, mixed, mesic Aridic Haplustalfs
Fragua	Coarse-loamy, mixed, mesic Aridic Haplustalfs
Frijoles	Loamy-skeletal over fragmental, mixed, mesic Aridic Haplustalfs
Galisteo	Fine, mixed, calcareous, mesic Ustic Torriorthents
Gilco	Coarse-loamy, mixed, calcareous, mesic Typic Torrifluvents
*Gilco	Coarse-loamy, mixed, calcareous, mesic Typic Torrifluvents
Grieta	Fine-loamy, mixed, mesic Typic Haplargids
Guaje	Medial-skeletal, mesic Aridic Ustochrepts
Hackroy	Clayey, mixed, mesic Lithic Haplustalfs
Hagerman	Fine-loamy, mixed, mesic Ustollic Haplargids
Harvey	Fine-loamy, mixed, mesic Ustollic Calciorthids
Hickman	Fine-loamy, mixed, calcareous, mesic Typic Ustifluvents
Ildefonso	Loamy-skeletal, mixed, mesic Ustollic Calciorthids
Jarmillo	Coarse-loamy, mixed Pachic Haploborolls
Jarola	Fine-loamy, mixed, frigid Typic Argialbolls
Jemez	Fine-loamy, mixed Mollic Eutroboralfs
Jocity	Fine-loamy, mixed, calcareous, mesic Typic Torrifluvents
La Fonda	Fine-loamy, mixed, mesic Ustollic Camborthids
Laventana	Loamy-skeletal, mixed Mollic Eutroboralfs
Lybrook	Fine, mixed, calcareous, mesic Ustic Torriorthents
Menefee	Loamy, mixed, calcareous, mesic, shallow Typic Ustorthents
Mespun	Mixed, mesic Ustic Torripsamments
Mirand	Fine, mixed Mollic Eutroboralfs
Montecito	Fine, mixed, mesic Aridic Haplustalfs
Nyjack	Fine-loamy, mixed, mesic Aridic Haplustalfs
Orejas	Clayey-skeletal, mixed, mesic Lithic Haplustalfs
Origo	loamy-skeletal, mixed Psammentic Cryoboralfs
Orlie	Fine-loamy, mixed, mesic Aridic Haplustalfs
Osha	Loamy-skeletal, mixed Typic Haploborolls
Palon	loamy-skeletal, mixed Psammentic Eutroboralfs
Pastura	Loamy, mixed, mesic, shallow Ustollic Paleorthids
Pavo	Fine-loamy, mixed Cryic Paleborolls
Penistaja	Fine-loamy, mixed, mesic Ustollic Haplargids

Table 19.--Taxonomic classification of the soils--continued

Soil name	Family or higher taxonomic class
Peralta	Coarse-loamy, mixed, calcareous, mesic Typic Ustifluvents
Pinavetes	Mixed, mesic Ustic Torripsamments
Pinitos	Fine-loamy, mixed, mesic Aridic Haplustalfs
Placitas	Loamy-skeletal, mixed, mesic Ustollic Calciorthids
Poley	Fine, mixed, mesic Ustollic Haplargids
Prieta	Clayey-skeletal, mixed, mesic Lithic Ustollic Haplargids
Querencia	Fine-loamy, mixed, mesic Ustollic Camborthids
Redondo	Loamy-skeletal, mixed Typic Cryoboralfs
Royosa	Mixed, mesic Typic Ustipsamments
Saido	Coarse-silty, gypsic, mesic Typic Gypsiorthids
San Mateo	Fine-loamy, mixed, calcareous, mesic Ustic Torrifluvents
Sandoval	Loamy, mixed, calcareous, mesic, shallow Ustic Torriorthents
Santa Fe	Loamy-skeletal, mixed, mesic Lithic Argiustolls
Sedgran	Sandy-skeletal, mixed, mesic Lithic Ustic Torriorthents
Sedillo	Loamy-skeletal, mixed, mesic Ustollic Haplargids
Sedmar	Sandy, mixed, frigid Lithic Ustorthents
Sheppard	Mixed, mesic Typic Torripsamments
Silver	Fine, mixed, mesic Ustollic Haplargids
Skyvillage	Loamy, mixed, calcareous, mesic Lithic Ustic Torriorthents
Sparank	Fine, mixed, calcareous, mesic Ustic Torrifluvents
Sparham	Fine, mixed, calcareous, mesic Typic Ustifluvents
*Sparham	Fine, mixed, calcareous, mesic Typic Ustifluvents
Stumble	Mixed, mesic Typic Torripsamments
Teco	Fine, mixed, mesic Aridic Haplustalfs
Tijeras	Fine-loamy, mixed, mesic Typic Haplargids
Tocal	Clayey, mixed Lithic Eutroboralfs
Totavi	Ashy, frigid Mollic Vitrandepts
Trail	Sandy, mixed, mesic Typic Torrifluvents
Tranquilar	Very-fine, montmorillonitic, frigid Typic Argialbolls
Tsosie	Fine-loamy, mixed, calcareous, mesic Ustic Torriorthents
Vastine	Fine-loamy over sandy or sandy-skeletal, mixed, frigid Typic Haplaquolls
Vessilla	Loamy, mixed, calcareous, mesic Lithic Ustorthents
Waumac	Coarse-loamy, mixed, calcareous, mesic Typic Ustorthents
Waumac Variant	Ashy-skeletal, mesic, shallow Typic Ustorthents
Wauquie	Loamy-skeletal, mixed, mesic Aridic Haplustalfs
Winona	Loamy-skeletal, carbonatic, mesic Lithic Ustollic Calciorthids
Witt	Fine-silty, mixed, mesic Ustollic Haplargids
Zia	Coarse-loamy, mixed, calcareous, mesic Ustic Torriorthents

NRCS Accessibility Statement

The Natural Resources Conservation Service (NRCS) is committed to making its information accessible to all of its customers and employees. If you are experiencing accessibility issues and need assistance, please contact our Helpdesk by phone at 1-800-457-3642 or by e-mail at ServiceDesk-FTC@ftc.usda.gov. For assistance with publications that include maps, graphs, or similar forms of information, you may also wish to contact our State or local office. You can locate the correct office and phone number at http://offices.sc.egov.usda.gov/locator/app.

Acknowledgments

This report culminates the implementation of the Hydrogeologic Workplan, approved by the New Mexico Environment Department in March 1998. The Workplan was sponsored by the U.S. Department of Energy and the University of California. It was written by an interdisciplinary group of contributing authors representing various Los Alamos National Laboratory divisions, programs, and projects. Many of these individuals were also contributing authors of this Hydrogeologic Synthesis Report. These authors were members of the Groundwater Integration Team (GIT) that was created to implement the Hydrogeologic Workplan.

Over the past eight years, many individuals, too numerous to mention, contributed to studies performed under the Workplan. In particular, contributions made by the GIT members were significant and are much appreciated. The leadership of Charles Nylander as Program Manager throughout the history of the Workplan is appreciated, as is the technical oversight provided by Bruce Robinson. The Hydrogeologic Synthesis Report was much improved by reviews by Alice Barr, Al Eddebbarh, June Fabryka-Martin, Don Hickmott, Ellen Louderbough, Everett Springer, and Ardyth Simmons. In addition, significant peer review of the Hydrogeologic Synthesis Report was provided by External Advisory Group (EAG) members, who were professionally involved in implementation of the Hydrogeologic Workplan, and their contributions are appreciated. The EAG members are Robert Charles, Elizabeth Anderson, Charles McLane, David Schafer, Robert Powell, and Jack Powers. We thank the staff of the Daniel B. Stephens and Associates Visual Resources Group for improving the quality of figures. Finally, the professional contributions made by Ardyth Simmons and Kelly Collins in completing the compilation and editing of this document are appreciated.

TABLE OF CONTENTS

EXECUTIVE SUMMARY ..... **xxi**

ABSTRACT **1-1**
1.0 INTRODUCTION **1-5**
1.1 Technical Objectives of the Hydrogeologic Workplan 1-7
1.2 Hydrogeologic Characterization Overview 1-7
1.3 Topical Organization 1-11

2.0 HYDROGEOLOGY **2-1**
2.1 Geologic Conceptual Model 2-1
2.1.1 Goals of the Geologic Model 2-5
2.1.2 Site-Wide Geology 2-5
2.1.2.1 Regional Setting 2-5
2.1.2.2 Structural Geology of the Pajarito Plateau 2-7
2.1.2.3 Volcanic Setting of the Pajarito Plateau 2-9
2.2 Stratigraphic Framework of the Pajarito Plateau 2-10
2.2.1 Tesuque Formation 2-19
2.2.2 Miocene Basalts 2-19
2.2.3 Older Fanglomerate 2-19
2.2.4 Totavi Lentil 2-20
2.2.5 Pumice-Rich Volcaniclastic Rocks 2-21
2.2.6 Tschicoma Formation 2-23
2.2.7 Puye Formation 2-23
2.2.8 Basaltic Rocks of the Cerros del Rio Volcanic Field 2-24
2.2.9 Bandelier Tuff 2-25
2.2.9.1 Otowi Member, Bandelier Tuff 2-26
2.2.9.2 Tephra and Volcaniclastic Sediments of the Cerro Toledo Interval 2-27
2.2.9.3 Tshirege Member, Bandelier Tuff 2-28
2.2.10 Alluvium and Colluvium 2-29
2.3 Geologic Conceptual Model Cross-Sections 2-30
2.3.1 Geology at the Water Table 2-30
2.3.2 Representative Cross-Sections 2-33
2.3.2.1 Los Alamos Canyon Cross-Section 2-43
2.3.2.2 Mortandad Canyon Cross-Section 2-43
2.3.2.3 Pajarito Canyon Cross-Section 2-44
2.3.2.4 Water Canyon Cross-Section 2-44
2.3.2.5 Western Boundary Cross-Section 2-45
2.3.2.6 West-Central Cross-Section 2-45
2.3.2.7 East-Central Cross-Section 2-46
2.3.2.8 Eastern Cross-Section 2-46
2.4 Hydrologic Properties 2-46
2.4.1 Vadose Zone Hydrologic Properties 2-47

2.4.2 Regional Aquifer Hydrologic Properties 2-49
2.4.2.1 Expected Lithologic Controls on Regional Aquifer Hydrologic Properties 2-50
2.4.2.2 Contact between Units 2-55
2.4.2.3 Regional Aquifer Hydraulic Conductivity 2-57
2.4.2.4 Anisotropy 2-69
2.4.2.5 Porosity 2-70
2.4.2.6 Storage Properities 2-72
2.4.3 Summary of Hydrologic Properties 2-72
2.4.4 Uncertainties in the Relationship between Geologic and Hydrogeologic Units 2-73
2.4.4.1 Extent and Nature of the Cerros del Rio Hydrogeologic Unit 2-74
2.4.4.2 Unassigned Pumice-Rich Volcaniclastic Rocks 2-74
2.4.4.3 Totavi Variants 2-74
2.4.4.4 Disposition of Santa Fe Group Sediments 2-75
2.4.4.5 Spatial Variation in Permeability within Sedimentary Rocks 2-75
2.4.4.6 Influence of Structure on Groundwater Flow 2-76
2.5 Alluvial Groundwater Conceptual Model 2-76
2.5.1 Physical Setting 2-77
2.5.2 Hydrology 2-77
2.5.2.1 Alluvial Recharge 2-78
2.5.2.2 Alluvial Aquifer Properties 2-84
2.5.2.3 Cerro Grande Fire Effects 2-85
2.6 Vadose Zone Conceptual Model 2-85
2.6.1 Climate and Infiltration 2-88
2.6.2 General Description of Conceptual Models 2-88
2.6.2.1 Mesas 2-89
2.6.2.2 Canyons 2-90
2.6.3 Vadose Zone Flow and Transport Mechanisms 2-91
2.6.4 Alternative Hypotheses 2-94
2.7 Perched Water 2-95
2.7.1 Perched Water Occurrence 2-95
2.7.2 Interpretation of Perched Water Observations 2-97
2.7.2.1 Surface Water Conditions for Perched Water 2-97
2.7.2.2 Geologic and Hydrostratigraphic Controls on Perched Water Occurrence 2-98
2.7.2.3 Subsurface Extent of Zones of Saturation 2-99
2.7.2.4 Flow Conditions Upstream and Within Intermediate Perched Groundwater Zones 2-99
2.8 Regional Aquifer Conceptual Model 2-101
2.8.1 Regional Hydrologic Setting 2-101
2.8.2 Hydrology Beneath the Pajarito Plateau 2-103
2.8.3 Water Budget 2-104
2.8.3.1 Recharge 2-104

2.8.8 Velocities and Travel Times 2-124

3.0 GROUNDWATER GEOCHEMISTRY, CONTAMINANT DISTRIBUTIONS, AND IMPLICATIONS FOR FLOW AND TRANSPORT 3-1
3.1 Geochemical Conceptual Model 3-1
3.1.1 Natural Chemical Composition of Groundwater 3-2
3.1.1.1 Geochemistry of the Recharge Zone 3-3
3.1.1.2 Aqueous Geochemistry along the Flow Path 3-3
3.1.1.3 Geochemistry of the Discharge Zone 3-7
3.1.2 Residence Times 3-8
3.1.3 Reactive Minerals Controlling Groundwater Composition and Solute Mobility 3-9
3.1.4 Adsorption and Precipitation Reactions 3-10
3.1.4.1 Adsorption and Precipitation of Uranium(VI) Species 3-12
3.1.5 Redox Conditions 3-16
3.1.6 Uranium Speciation 3-17
3.1.7 Summary of Geochemical Conceptual Model 3-19
3.2 Contaminant Distributions and Transport 3-22
3.2.1 Contaminant and Constituent Sources 3-27
3.2.2 Water Inputs 3-27
3.2.3 Hydrogeologic Controls 3-28
3.2.3.1 Infiltration Rate and Transport in Alluvial Groundwater 3-29
3.2.3.2 Vadose Zone Pathways and Transport in Intermediate Groundwater 3-36
3.2.3.3 Flow Field Modification and Transport in Regional Aquifer Groundwater 3-43
3.2.4 Off-Site Transport 3-44
3.2.5 Summary of Contaminant and Transport 3-47

4.0 NUMERICAL MODELS 4-1
4.1 Site-Wide Vadose Zone Flow and Transport Model 4-1
4.1.1 Model Development 4-1
4.1.1.1 Flow and Transport Processes 4-2
4.1.1.2 Infiltration Rate 4-2
4.1.1.3 Numerical Model Implementation 4-3
4.1.2 Model Results 4-5

4.1.2.1 Base-Case Results 4-5
4.1.2.2 Uncertain Infiltration Rate 4-6
4.1.2.3 Perched Water Conceptual Uncertainty 4-8
4.1.3 Contaminant Transport Model Predictions—Representative Canyon and Mesa Sites 4-10
4.1.3.1 MDA G Model 4-10
4.1.3.2 Los Alamos Canyon Model 4-13
4.2 Numerical Models of Flow and Transport in the Regional Aquifer 4-19
4.2.1 Previous Numerical Models 4-19
4.2.2 Overview of LANL Model Development 4-21
4.2.3 Numerical Framework 4-22
4.2.4 Hydrostratigraphy 4-23
4.2.5 Boundary Conditions 4-25
4.2.6 Recharge 4-25
4.2.7 Discharge at Rivers and Interbasin-Flow 4-27
4.2.8 Lateral Boundaries of the Site-Scale Model 4-27
4.2.9 Data Used in Model Development and Testing 4-29
4.2.10 Flow Model Parameters 4-29
4.2.11 Transport Model Methods and Parameters 4-30
4.2.12 Model Applications 4-35
4.2.12.1 Category A: Integrate and interpret 3-D site-wide hydrologic and hydrostratigraphic data, to provide a more quantitative basis for testing site-wide conceptual models than was previously possible. 4-35
4.2.12.2 Category B: Predict fate and transport of contaminants in the regional aquifer, in order to optimally place monitoring wells and inform risk assessment studies. 4-50
4.2.12.3 Category C: Provide guidance in prioritization of data collection activities, highlighting the importance of those data that could most reduce numerical and conceptual model uncertainty. 4-55

5.0 CONCLUSIONS 5-1
5.1 Summary 5-1
5.1.1 Presence of Contaminants 5-1
5.1.2 Water Inputs 5-3
5.1.3 Vadose Zone Hydrogeologic Controls 5-4
5.1.4 Regional Aquifer Transport 5-6
5.2 Relation of Hydrogeologic Workplan Results to Risk Assessment 5-8
5.3 Implications of Hydrogeologic Workplan Findings for Monitoring 5-10
5.3.1 Alluvial Groundwater 5-11
5.3.2 Vadose Zone 5-12
5.3.3 Regional Aquifer 5-15

Los Alamos National Laboratory's Hydrogeologic Studies of the Pajarito Plateau: A Synthesis of Hydrogeologic Workplan Activities (1998–2004)

edited by

Kelly A. Collins, Ardyth M. Simmons, Bruce A. Robinson, and Charles L. Nylander

ABSTRACT

This report provides a comprehensive description of the hydrogeologic setting beneath the Pajarito Plateau and Los Alamos National Laboratory (LANL). It is based on interpretative synthesis of hydrogeologic and geochemical data collected through December 2004. Since 1998, twenty-five regional aquifer wells and six intermediate-zone wells have been completed for hydrogeologic characterization. Characterization of the hydrogeologic setting was undertaken in order to fulfill regulatory requirements for characterization and monitoring. This report provides the data and information necessary to evaluate the existing monitoring network and, if necessary, to design an enhanced monitoring network.

Los Alamos National Laboratory (LANL) is situated on the Pajarito Plateau, located within the Española Basin section of the Rio Grande Rift. The Española Basin, as well as the Pajarito Plateau on its western edge, is filled with Miocene and Pliocene-age sediments and volcanic rocks. The topographic plateau is formed by Pleistocene Bandelier Formation ash-flow tuffs from the Jemez volcanic field, which cover the basin-fill sediments.

Groundwater occurs in three settings beneath the Pajarito Plateau: alluvial groundwater, intermediate-perched saturated zones, and the regional aquifer. Alluvial groundwater occurs to a limited and variable extent in the alluvium lining canyon bottoms. Alluvial groundwater provides pathways for LANL-derived contamination introduced into canyons to migrate to significant lateral distances and infiltrate to greater depths.

Flow and transport of water in the vadose zone varies by rock type. Most of the plateau is covered with nonwelded to moderately welded Tshirege and Otowi Member ash-flow tuffs of the Bandelier Tuff. Unsaturated flow and transport through these nonwelded to moderately welded tuffs occurs predominantly through the porous matrix. On the western edge of the plateau, both fracture and matrix-dominated flow can occur, depending on the degree of welding (or matrix conductivity) of the tuff. In contrast to the flow behavior in the Bandelier Tuff units, much of the vadose zone flow through the basalt units is almost certainly fracture dominated. Beneath the Pajarito Plateau, perched water bodies in the vadose zone may be important components of subsurface pathways that facilitate movement of contaminated fluids from the ground surface to the water table of the

regional aquifer. Perched water is most often found in Puye fanglomerates, the Cerros del Rio basalt, and in units of the Bandelier Tuff.

The regional aquifer beneath the Pajarito Plateau is part of an aquifer which extends throughout the Española Basin (an area roughly 6000 km2). This aquifer is the primary source of water for the Laboratory, the communities of Santa Fe, Española, Los Alamos, and numerous pueblos. The sources of recharge to the regional aquifer are diffuse recharge in the Sierra de los Valles and focused recharge from wet canyons on the Pajarito Plateau. Natural discharge from the regional aquifer is primarily into the Rio Grande directly or to springs that flow into the Rio Grande. The aquifer is under water-table conditions across much of the Plateau, but exhibits more confined aquifer behavior near the Rio. Hydraulic properties are highly anisotropic, with vertical hydraulic conductivities much smaller than horizontal hydraulic conductivites, resulting in a muted response at the water table to supply-well pumping at greater depths. Flow modeling simulations suggest that flow beneath the Rio Grande (west to east) has been induced by production at the Buckman wellfield just east of the Rio Grande, which supplies the city of Santa Fe. Because of the heterogeneous nature of the aquifer, groundwater velocity varies considerably over short distances. The fastest velocities are in the basalts where fracture flow is assumed.

Imprinted on the natural variations in chemistry along flowpaths is the presence of contaminants historically released since the early 1940s when Laboratory operations commenced. The impacts to groundwater at the Laboratory have occurred mainly where effluent discharges have caused increased infiltration of water. The movement of groundwater contaminants is best seen through the distribution of conservative (that is, non-reactive) chemical species. Under many conditions, compounds like RDX, tritium, perchlorate, and nitrate move readily with the groundwater. In many settings, chemical reactions do not retard the movement of these compounds or decrease their concentrations, although the activity of tritium does decrease due to radioactive decay. For some compounds or constituents (uranium, strontium-90, barium, some HE compounds, and solvents), movement is slowed or their concentrations are decreased by adsorption or cation exchange, precipitation or dissolution, chemical reactions like oxidation/reduction, or radioactive decay. Other constituents (americium-241, plutonium, and cesium-137) are nearly immobile because they are strongly adsorbed onto sediment particles.

The distribution of tritium in the regional aquifer supports the conceptual model that surface effluent discharges have caused the cases where Laboratory contaminants are found at depth. In most cases, the highest regional aquifer tritium values are found near where effluent discharges have occurred, but are much lower than values observed in overlying alluvial or intermediate perched groundwater. The lower regional aquifer values may be due to dilution of recharge by other groundwater sources as well as radioactive decay due to recharge times of decades.

The conceptual models of the hydrologic system beneath the Pajarito Plateau have been translated into numerical models. A site-wide model for performing first-order analysis of travel time through the vadose zone across the entire Pajarito Plateau was used to identify areas where contaminant pathways are likely to exist. Results indicated that the predicted travel times on mesas are variable, but for the

most part are greater than 1000 years, ranging from 1000–5000 years in the eastern portions of the Laboratory to 20,000 to 30,000 years in the western region. Two factors control these results: infiltration rate and hydrostratigraphy. Generally, travel times less than 100 years are predicted in the portions of canyons with net infiltration of 300 mm/yr to 1000 mm/yr, especially in locations where the Bandelier Tuff is thin.

The regional aquifer model has been applied to predict fate and transport of contaminants in the regional aquifer, in order to optimally place monitoring wells and inform risk assessment studies; and to provide guidance in prioritization of data collection activities.

Armed with the understanding gained from the Hydrogeologic Workplan activities, it is now possible to develop improved groundwater monitoring strategies or conduct more cost-effective detailed studies of individual canyons where initial studies have suggested that groundwater risk may exist.

1.0 INTRODUCTION

This report provides a comprehensive description of the hydrogeologic setting beneath the Pajarito Plateau and Los Alamos National Laboratory (LANL). It is based on interpretative synthesis of hydrogeologic data collected through December, 2004. Characterization of the hydrogeologic setting was undertaken in order to fulfill regulatory requirements for characterization and monitoring. This report provides the data and information necessary to evaluate the existing monitoring network and, if necessary, to design an enhanced monitoring network. Monitoring network evaluation and design are not addressed in this report. Recommendations included in this report are for scientific interest only, and are not necessary to comply with the regulatory requirements.

LANL is located in Los Alamos, Santa Fe, and Sandoval counties of north-central New Mexico, roughly 25 mi northwest of Santa Fe (Figure 1-1). It is owned by the Department of Energy (DOE) and co-operated by DOE and the University of California (UC). Work at LANL began in 1943 with the mission to design, develop, and test nuclear weapons.

Beginning in 1945, the US Geological Survey (USGS) became involved in various studies to develop the water supply at LANL (LANL 1995). Special studies to protect and monitor groundwater quality were initiated by LANL in 1949. Thus, groundwater monitoring has been conducted at LANL for over 50 years. The first monitoring network was limited to the water supply wells, a handful of test wells, and springs. The monitoring network evolved as environmental programs, such as those managed by LANL's Environmental Restoration (ER) organization (now Environmental Stewardship—Environmental Remediation & Surveillance Program [ENV-ERS]), added more wells, primarily in the shallow alluvial systems, as potential monitoring points.

In 1997, LANL personnel began a site-wide hydrogeologic characterization program, which is described in the Hydrogeologic Workplan (LANL 1998). The primary objective of the characterization program was to sufficiently refine the understanding of the hydrogeologic systems so that, if appropriate, an enhanced monitoring network could be designed. The Hydrogeologic Workplan was implemented, resulting in installation of 25 regional aquifer wells. Data from sampling and measurements taken at these wells have provided information about the subsurface geologic environment, including the vadose zone and intermediate perched and regional aquifer groundwater. This report is a synthesis of data from Hydrogeologic Workplan activities and all other groundwater-related investigations conducted at LANL since 1997. Collection and analysis of groundwater data is ongoing at LANL, associated with site-specific (not site-wide) investigations. It is considered unlikely that information from wells drilled after December 2004 will significantly change the understanding of the site-wide hydrogeologic setting described in this report. In some cases, analysis and interpretation of data lags behind data collection, and what is presented here does not include analysis of all data collected up to December 2004. Analysis of the data collected as part of the site-wide characterization has sufficiently improved the understanding of the hydrogeologic system and the ability to design and implement an integrated site-wide groundwater monitoring program.

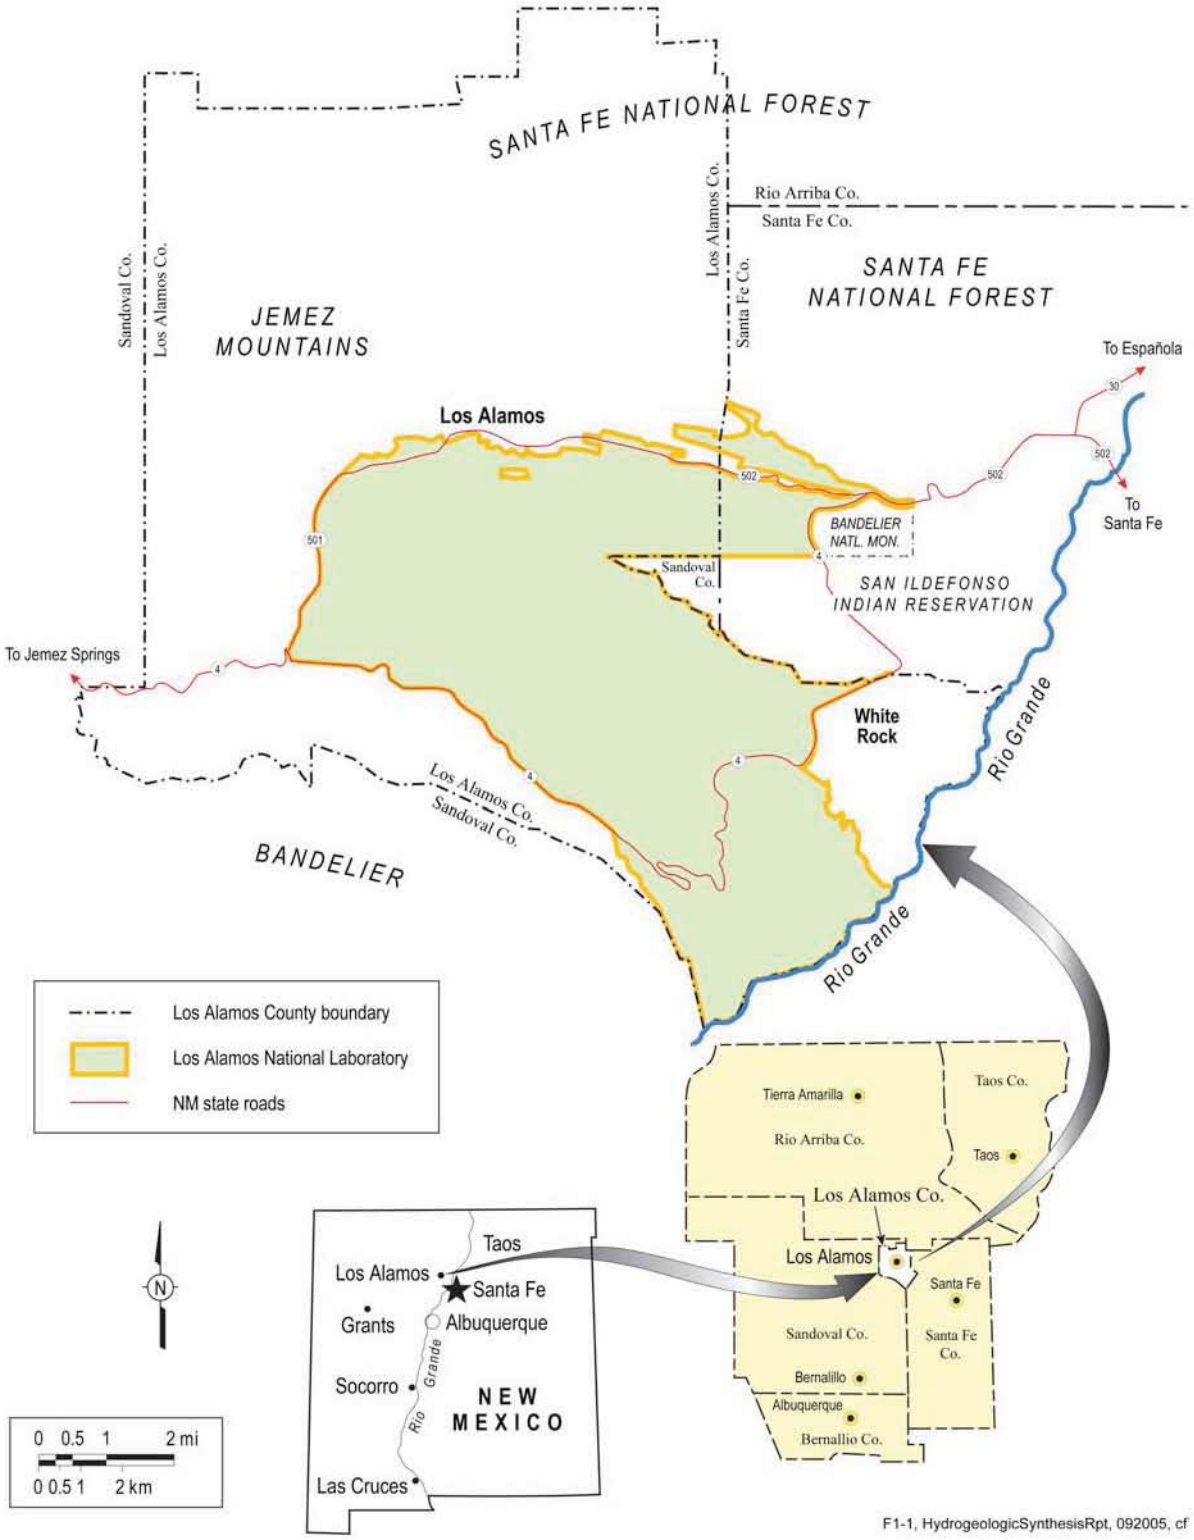

Figure 1-1. Location of Los Alamos National Laboratory.

1.1 Technical Objectives of the Hydrogeologic Workplan

The primary technical objective of the Hydrogeologic Workplan was to collect data necessary to evaluate and, if necessary, enhance the groundwater monitoring network at LANL. The technical objectives of the Hydrogeologic Workplan were intended to be comprehensive with respect to groundwater regulatory requirements for characterization and monitoring, described in Appendix 1-A. The regulatory requirements included

- Resource Conservation and Recovery Act (RCRA) operating permit which requires monitoring for RCRA units, unless a groundwater monitoring waiver is demonstrated.
- New Mexico Environment Department (NMED) letters requiring a better understanding of the hydrogeologic regime in order evaluate groundwater monitoring waivers submitted by LANL.
- RCRA permits Hazardous and Solid Waste Amendments (HSWA) module requirements to characterize the hydrogeologic setting.

Specifically, NMED identified four issues that needed to be resolved in order to evaluate the groundwater monitoring waivers submitted by LANL (Appendix 1-A):

- Individual zones of saturation beneath LANL had not been adequately delineated and the "hydraulic interconnection" between these was not understood.
- The recharge area(s) for the regional and intermediate aquifers and any associated effects of fracture-fault zones with regard to contaminant transport and hydrology had not been identified.
- The groundwater flow direction(s) of the regional aquifer and intermediate aquifers, as influenced by pumping of production wells, were unknown.
- Aquifer characteristics could not be determined without additional monitoring wells installed within specific intervals of the various aquifers beneath the facility.

Table 1-1 is a crosswalk of HSWA module requirements for groundwater characterization, how they have been addressed, and which sections of this report contain that information.

1.2 Hydrogeologic Characterization Overview

In order to establish the data quality objectives that guided the development of the Hydrogeologic Workplan (LANL 1998), the information needed to evaluate and design a monitoring network was articulated. Groundwater at LANL occurs in three modes: alluvial, perched intermediate groundwater in the vadose zone, and the regional aquifer. Figure 1-2 shows the relationship between the Pajarito Plateau topography and modes of groundwater. In general, to monitor the quality of water that has the potential to be impacted by releases of hazardous or radioactive wastes, there must be an understanding of the following:

Table 1-1.
Crosswalk Between HSWA Permit Requirements* and Synthesis Report Section

HSWA Permit Reference	Permit Requirement	Synthesis Report Sections
Task III.A.1.a	A description of the regional and facility specific geologic and hydrogeologic characteristics affecting groundwater flow beneath the facility	Section 2.2, Section 2.4
Task III.A.1.b	An analysis of any topographic features that might influence the groundwater flow system	Section 2.1.3
Task III.A.1.c	An analysis of fractures within the tuff, addressing tectonic trend fractures versus cooling fractures	Section 2.5.4
Task III.A.1.d	Based on field data, tests, (gamma and neutron logging of existing and new wells, piezometers, and borings) and cores, a representative and accurate classification and description of the hydrogeologic units which may be part of the migration pathways at the facility (e.g., the aquifers and any intervening saturated and unsaturated units)	Section 2.3; Section 4.2.12
Task III.A.1.e	Based on field studies and cores, structural geology and hydrogeologic cross sections showing the extent (depth, thickness, lateral extent) of hydrogeologic units which may be part of the migration pathway identifying Unconsolidated sand and gravel deposits Zones of fracturing or channeling in consolidated and unconsolidated deposits Zones of high or low permeability that might direct and restrict the flow of contaminants	Section 2.3; Section 4.1.2; Section 4.2.12
Task III.A.1.f	Based on data obtained from groundwater monitoring wells and piezometers installed upgradient and downgradient of the potential contaminant source, a representative description of water level or fluid pressure monitoring	Section 2.4.2
Task III.A.1.g	A description of manmade influences that may affect the hydrogeology of the site	Section 2.7.6
Task III.A.1.h	Analysis of available geophysical information and remote sensing information such as infrared photography and Landsat imagery	Appendix 2-A
Task III.A.2.d	Characterize rock and soil units above the water table including saturated hydraulic conductivity	Section 2.2, Section 2.3, Section 2.4.1
Task III.A.2.e	Characterize rock and soil units above the water table including porosity	Section 2.2, Section 2.3, Section 2.4.1

- Potential sources of contaminants: contaminant character, inventory, and locations
- Release mechanisms that introduce contaminants to the environment
- Contaminant transport mechanisms from the location of the release to groundwater
- Transport of contaminants through the groundwater system: direction and velocity of groundwater and of contaminants

Monitoring data needs were identified for each component of the groundwater system: alluvial, intermediate perched groundwater in the vadose zone, and regional aquifer and the connections between the components. Figure 1-2 shows the overall hydrogeologic conceptual model. In wet canyons, where surface water is present, the water infiltrates the alluvium in the canyon bottoms and forms alluvial groundwater. Dry canyons and mesas do not have alluvial groundwater. Alluvial groundwater flows down the canyon until it reaches an area where infiltration is enhanced by thin or absent Bandelier Tuff, highly fractured rock below the alluvium, or anthropogenic alterations (e.g. sediment traps). In areas with enhanced infiltration, alluvial groundwater percolates through the vadose zone and collects in relatively more permeable units, if there are any present beneath the canyon, e.g. fractured basalt. Alluvial groundwater and perched intermediate groundwater continue to percolate through the deeper vadose zone until they reach the regional

aquifer. The interconnected nature of the hydrogeologic system may allow anthropogenic constituents that are present in surface water to be transported into alluvial groundwater, the vadose zone and to the regional aquifer.

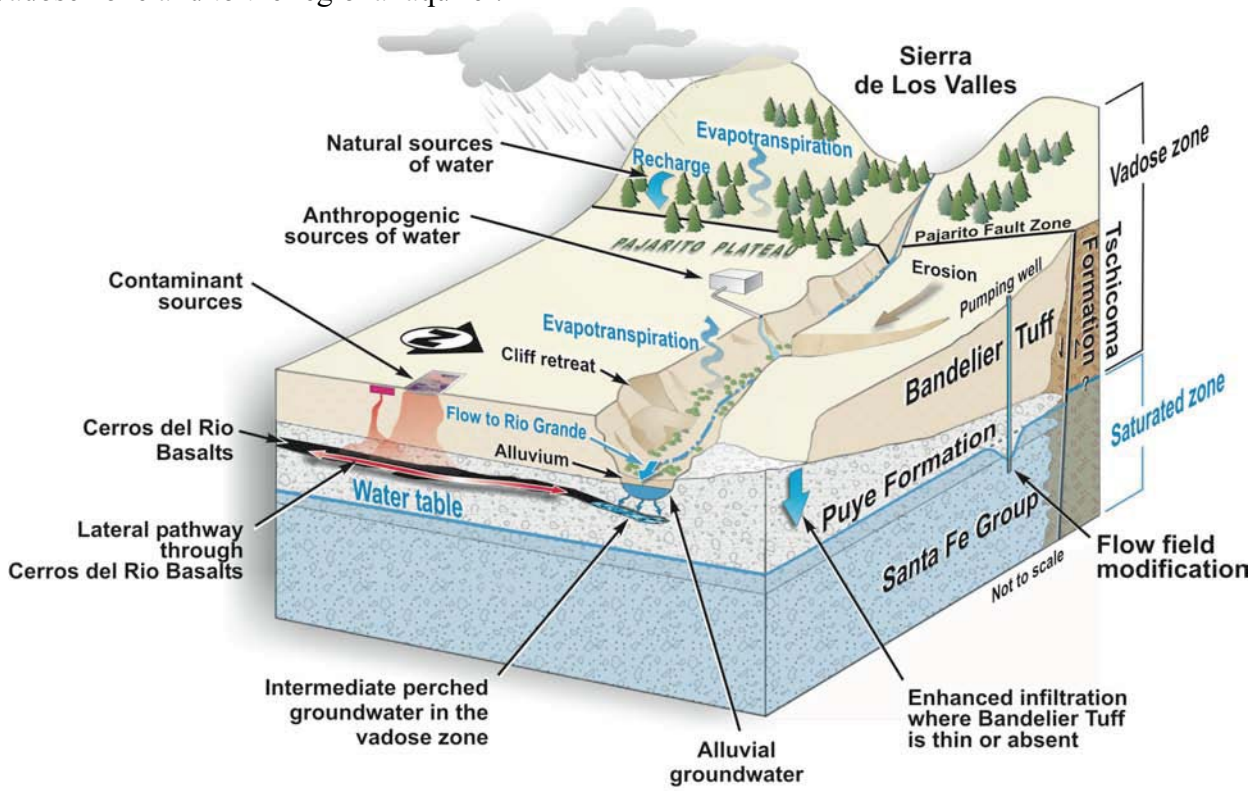

Figure 1-2. Groundwater components at LANL.

The data collection articulated in the Hydrogeologic Workplan considered elements of risk assessment, e.g. sources, release mechanisms, and transport, because these same elements are important in establishing a monitoring network capable of detecting releases. Thus, the data collected under the auspices of the Hydrogeologic Workplan are considered adequate to support risk assessment, but are not intended to serve as a risk assessment. Characterizing the source terms and release mechanisms or other chemical phenomena is the subject of ongoing investigations and information from those investigations was used in developing the Hydrogeologic Workplan (LANL 1998). Characterizing the alluvial component of the hydrologic system was undertaken in conjunction with investigating source terms and the results of the alluvial investigations are reported here (Section 2.4) because of the importance of alluvial groundwater in the hydrogeologic system. The primary focus of the Hydrogeologic Workplan (LANL 1998) activities was on the deeper groundwater components and to understand the movement of contaminants through the vadose zone and in the regional aquifer.

Since 1998, twenty-five regional aquifer wells and six intermediate-zone wells have been completed for hydrogeologic characterization (Table 1-2). The locations of the hydrogeologic characterization wells are shown on Figure 1-3. Well completion fact sheets (Appendix 1-B) and well completion reports document the drilling, well construction, well completion, testing, and

sampling for each characterization well. A description and analysis of the characterization sampling for many wells are documented in geochemistry reports.

1.3. Topical Organization

The most basic control on the movement of water and contaminants through the system is the rocks through which the water moves. The conceptual model of the site is built from surface and subsurface geologic data (Appendix 2-A). Section 2.1 describes the regional geologic setting as a context for understanding the stratigraphic framework of the Pajarito Plateau presented in Section 2.2. Cross sections that illustrate the relationship between the stratigraphic units are critical for understanding how groundwater flows (Section 2.3).

The hydrologic properties of stratigraphic units in the vadose zone and regional aquifer are described in Section 2.4. This section quantifies the properties of the hydrologic units and explains the sources of data, including the uncertainties in the properties. The hydrologic properties and processes are combined to create conceptual models of the alluvial, vadose zone, and regional aquifer components in Sections 2.5, 2.6 and 2.7, respectively.

The natural groundwater geochemistry of the Pajarito Plateau is important to understand in order to identify and quantify contaminants added to the system. The background groundwater chemistry is integrated with geochemical processes to provide the comprehensive geochemical model described in Section 3.1. Overprinted on the natural water chemistry are the contaminants potentially released by LANL activities. Section 3.2 synthesizes the contaminant distribution data with respect to hydrologic processes and explores the contaminant transport implications.

Numerical modeling is an analytical tool that can be used to integrate and synthesize the sometimes widely-spaced point hydrogeologic field data and that predicts how the hydrologic system will behave at different times and under different conditions in the future. However, before models can be used for prediction, they must adequately reproduce the current conditions. The vadose zone and regional aquifer models that have been developed adequately reproduce current conditions beneath the Pajarito Plateau are described in Sections 4.1 and 4.2. These sections include the underlying assumptions, hydrologic processes, calibration, and predictions for flow and transport.

Section 5 summarizes the information presented in Sections 2, 3 and 4 and highlights how the refined understanding of the hydrogeologic systems can be applied to evaluating the adequacy of the existing the monitoring system and, if necessary, the design of an enhanced monitoring network.

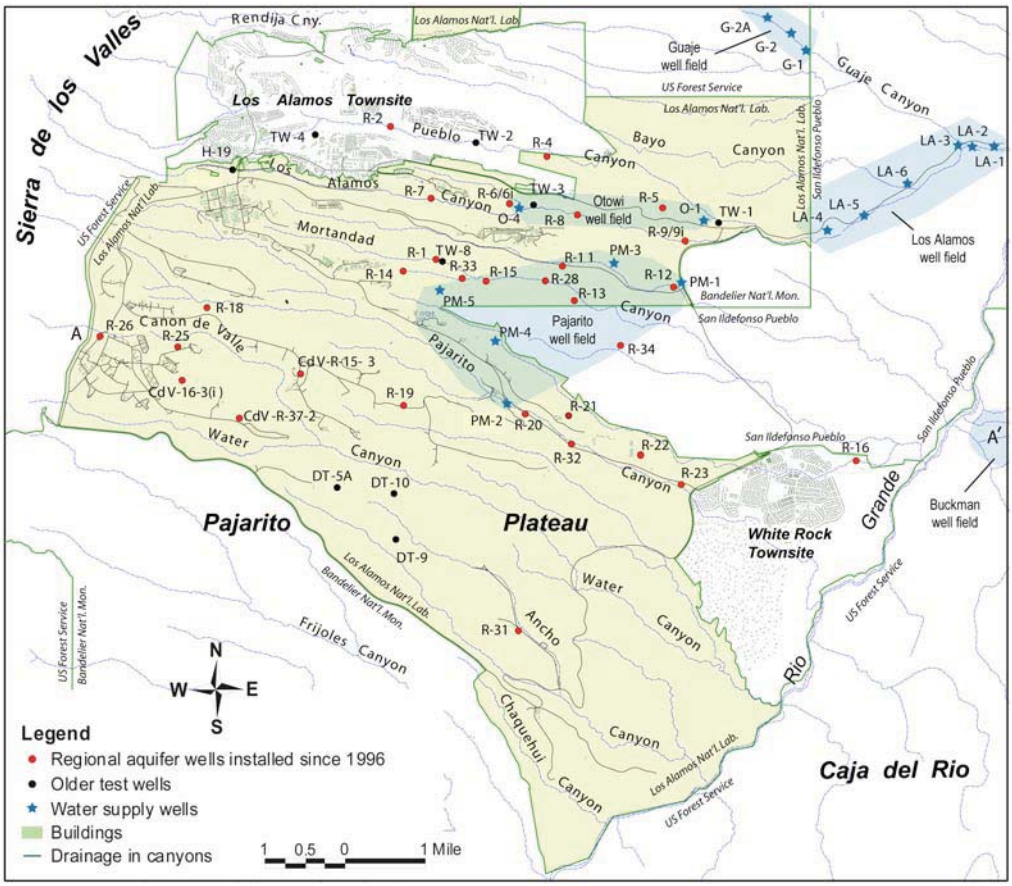

Figure 1-3. Locations of the Hydrogeologic Workplan characterization wells.

2.0 HYDROGEOLOGY

Groundwater occurs in three settings beneath the Pajarito Plateau: alluvium, intermediate perched saturated zones, and the regional aquifer. The major source of recharge to the regional aquifer is precipitation within the Sierra de los Valles. However, alluvial groundwater on the Pajarito Plateau is a source of recharge to underlying intermediate perched saturated zones and to the regional aquifer.

This section describes the conceptual understanding of the hydrogeology beneath the Pajarito Plateau. The conceptual models of the hydrogeologic system described here are based on empirical observations combined with knowledge of geologic and hydrologic processes. These conceptual models are the foundation of the numerical models described in Section 4. First, the geologic conceptual model is described to provide an understanding of the geologic units that are present. Second, the connection between geology and hydrology is discussed because the geology is the first-order control on the Pajarito Plateau hydrology. Finally, the conceptual models for the alluvial groundwater, perched intermediate groundwater, and the regional aquifer are described.

2.1 Geologic Conceptual Model

The geologic conceptual model for the LANL site is developed from (1) past studies of site and regional geology that predate implementation of the Hydrogeologic Workplan, including over 50 years of mapping, drilling, and regional geophysical studies; (2) borehole data collected specifically for the Hydrogeologic Workplan; and (3) integration of results from current Hydrogeologic Workplan studies with other studies in the region, particularly those that are brought together by the Española Basin Technical Advisory Group. Table 2-1 provides a summary of the types of information used to develop the geologic conceptual model and Appendix 2-A contains a detailed description of the geologic types of data used to develop the conceptual model.

There are localized subsurface geologic data associated with drilling boreholes and regional geologic data, surface and subsurface, which are obtained by aerial surveys and work done by others on a regional scale. The localized subsurface geologic data are obtained from:

- Cuttings and core
- Borehole geophysical data
- Borehole video logs
- Drilling rates and character

.

Table 2-1.
Summary of Geologic Data

Data Type	Purpose	Data Collection	Data Records	Archives
Lithologic Information from Cuttings	Direct measurements of the top and bottom and character of the hydrogeologic units at each borehole. Correlations of rock units among boreholes are key components of the site-wide 3-D geologic model for the plateau.	Approximately 500 to 700 ml of bulk drill cuttings were collected every 5 ft, as conditions permitted, to the total depth (TD) of each boring. Cuttings were visually examined and a small subset of core and cuttings was selected for additional characterization: X-ray diffraction for mineralogy, X-ray fluorescence for rock chemistry, thin-section petrography, and $^{40}Ar/^{39}Ar$ age dating.	Lithologic logs summarize rock lithologies, alteration features, and stratigraphic contacts from visual examination and interpretations of borehole geophysical logs.	Core and cuttings are currently archived at the ENV Division Sample Management Facility located at Technical Area 3, building 03-0271-101. All borehole materials are stored in core boxes labeled with the well name, box number, and footage range for the box.
Lithologic Information from Core	Core was collected to fulfill a number of characterization objectives, including: • geology of perched saturated zones and aquitards • hydrologic and chemical analyses of vadose-zone samples (e.g. moisture, anions) • hydraulic properties of selected hydrogeologic units.	Core was collected from dedicated core holes and from selected intervals in some regional aquifer boreholes.	Same as for cuttings above.	Same as for cuttings above

Table 2-1.
Summary of Geologic Data (continued)

Data Type	Purpose	Data Collection	Data Records	Archives
Drilling Information	Observations about drilling characteristics by the drillers and on-site geologists contributed to understanding the hydrogeology of the boreholes.	Major lithologic and stratigraphic contacts were commonly marked by significant changes in drill penetration rates. Drilling rates are primarily affected the competency of the rocks being penetrated. Hard rock units have slow drilling rates, whereas less-competent rocks were drilled more rapidly. Important information about water-bearing strata was obtained when drillers noted changes in the drilling fluids circulating through the borehole.	These observational data were recorded in field logs, and they provided supplemental information that aided the interpretation of hydrogeologic data from other sources such as cuttings and geophysical logs.	N/A
Borehole Geophysical Data	Determine the geologic and hydrologic characteristics of the vadose zone, perched saturated zones, and regional aquifer. Preliminary logs were used by contractor, DOE, and LANL personnel to help select well screen locations and to evaluate borehole conditions prior to well construction.	*LANL*: caliper, spontaneous potential, single-point resistance and induction, and natural gamma radiation logs. *Contractor:* wire-line logging service was contracted to obtain a more extensive suite of borehole geophysical logs once the borehole reached total depth	Preliminary results of geophysical logs were generated in the logging truck at the time the geophysical services were performed. Contractor reprocessed the field measurements to correct them and to combine the logs into a single presentation enabling integrated interpretation.	Results of contractor geophysical logging and analysis are summarized in an interpretive report that is included in each well completion report.

Table 2-1.
Summary of Geologic Data (continued)

Data Type	Purpose	Data Collection	Data Records	Archives
Borehole Video Logs	To obtain lithologic information and to help determine stratigraphic contacts; visual examination of borehole walls for evidence of perched saturation; document water levels in the boreholes; document the as-built condition of installed well components; assess the effectiveness of well development techniques; to assess problematic borehole conditions and to guide fishing operations for tools and equipment lost downhole.	Borehole video was used in each borehole or completed well. The videos were viewed by geologists to assess geologic conditions. Often used in conjunction with geophysical logs to determine the locations of perched zones in some boreholes and the presence and nature of fractures.	Video logs were collected during installation of workplan wells.	N/A
Regional Airborne Surveys	Focus groundwater investigations by defining the conductivity structure beneath the plateau. Gravity data were used to help define regional structure beneath the Pajarito Plateau.	A total of 762 line kilometers of MegaTEM® time domain EM data and magnetic data were collected (80% of LANL area). Flight lines spaced at 105 m within the laboratory boundaries, and at 210 m in buffer zones. Lines oriented N20E, with tie lines about 2000-meter spacing.	Maps of Residual Magnetic Intensity (RMI), apparent conductance and conductivity depth slices at various depths, multiparameter profiles with conductivity-depth-transform (CDT) sections for flight lines and digital archives of line and grid data.	All of the processing assumed a "layered-earth" model, and inversions were: single points/multiple depths (1-D), multiple depths along individual flight lines (2-D), or a constant depth on multiple flight lines (2-D). The results of all three models, for each flight line are available as Adobe PDF files.

Note: N/A = not applicable

Geologic data derived from regional-scale studies were obtained from multiple sources, including:

- Surface geophysical data were used to help constrain the site-wide geologic model (Appendix 2-A). These data include regional gravity data, airborne electromagnetic data, high resolution resistivity, and magnetotellurics. Gravity data were used to help define regional structure beneath the Pajarito Plateau. Airborne electromagnetic data, high resolution resistivity, and magnetotelluric data were used to focus groundwater investigations by defining the conductivity structure beneath the plateau
- Numerous local and regional mapping projects and geological studies have provided important information supporting development of geologic conceptual models and digital realizations of these models.
- Española Basin workshops were hosted annually by the Española Basin Technical Advisory Group and sponsored by the U.S. Geological Survey, the New Mexico Bureau of Geology and Mineral Resources, Los Alamos National Laboratory, and the city of Santa Fe.
- The Seismic Hazards program at LANL was an important source of information about faults and fractures in the vicinity of the Laboratory.
- Students and their advisors from the graduate programs from the University of New Mexico and New Mexico State University, New Mexico Institute of Mining and Technology, and the University of Texas have provided additional hydrogeologic information for the Jemez volcanic field, the Espanola Basin, and the Puye Formation.

2.1.1 Goals of the Geologic Model

- Define the geologic setting of the groundwater system beneath the Pajarito Plateau
- Relate lithologic properties of rocks to groundwater flow characteristics and rock/water interactions
- Provide a benchmark for comparing new data to predicted geology
- Improve selection of new well sites based on iterative evaluation of hydrogeologic information
- Provide a framework for numerical flow and transport models of the vadose and saturated zones

2.1.2 Site-Wide Geology

The discussion of site-wide geology presented here is condensed from a summary by Broxton and Vaniman (2005). More detailed, fully referenced information is available in that publication. The deep characterization wells drilled in the time period from 1997 to 2004 have provided the foundation for constructing the geologic framework surfaces presented in this section.

2.1.2.1 Regional Setting

The Pajarito Plateau lies at the volcanically and seismically active boundary between the Colorado Plateau and the Rio Grande Rift in north-central New Mexico (Figure 2-1). The Rio Grande rift is a major geologic feature that consists of north-trending, fault-bounded basins

extending from central Colorado to northern Mexico. The local area of subsidence, termed the Española Basin, lies between two larger basins—the Albuquerque Basin to the south and San Luis Basin to the north (Kelley, 1978). The Española Basin is about 70 km (44 mi) long and 60 km (37 mi) wide. The plateau overlies the deepest part of the west-tilted Española Basin adjacent to the highlands of the Jemez volcanic field. Geologic units consist of Miocene and Pliocene basin-fill deposits and interfingering volcanic rocks from the Jemez and Cerros del Rio volcanic fields. Miocene and Pliocene sedimentary and volcanic rocks are covered by Pleistocene ash-flow tuffs making up the Pajarito Plateau.

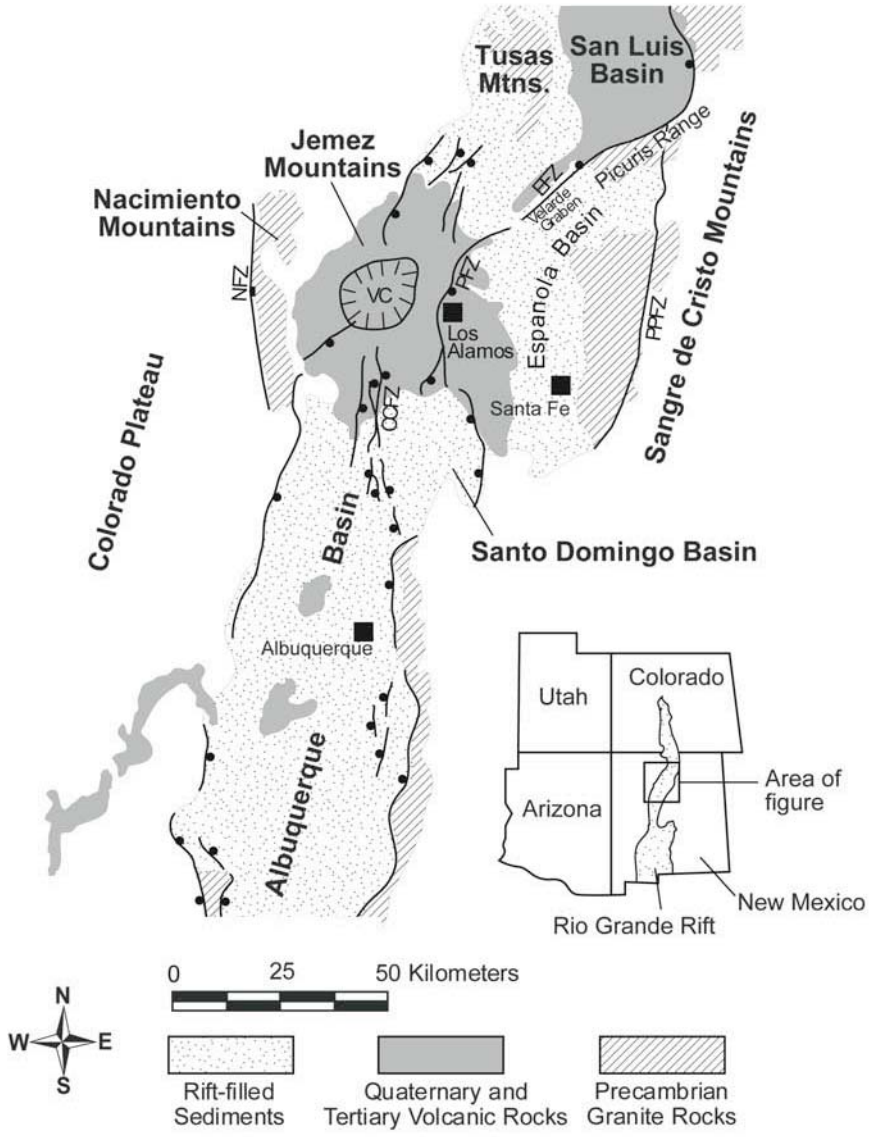

Figure 2-1. Locations of major structural and geologic elements near LANL. Major fault systems are shown with ball on downthrown side. VC is the Valles Caldera complex; NFZ is the Nacimiento fault zone; CCFZ is the Cañada del Cochiti fault zone; PFZ is the Pajarito fault zone; and PPFZ is the Picuris-Pecos fault zone.

The western structural margin of the Española Basin is partly covered by rocks of the Jemez volcanic field, but probably includes a broad zone of north-trending faults such as the Cañada de Cochiti fault zone (Figure 2-1) that cut older volcanic units in the south-central part of the volcanic field (Gardner and Goff, 1984). The present active western boundary of the Española Basin is the Pajarito fault zone, a narrow band of north- and northeast-trending normal faults that delineate the western margin of the Pajarito Plateau. Neogene displacement along the Pajarito fault zone is dominantly down to the east with episodic faulting indicated by progressively larger offsets in older rock units.

Gravity data (Biehler et al., 1991; Ferguson et al., 1995) indicates the deepest part of the Española Basin coincides with three deep, intrabasinal grabens arrayed along the Pajarito and Embudo fault systems. From north to south, these subbasins include the Velarde graben (Manley, 1979, 1984), a north-northeast trending basin beneath Santa Clara pueblo, and a north-trending basin near Los Alamos. The Pajarito fault zone forms the western boundary of the Los Alamos subbasin (Biehler et al., 1991; Ferguson et al., 1995; Smith, 2004). Gravity data suggest that the eastern boundary is bounded by buried faults that lie east of the southern projections of the Rendija Canyon and Guaje Mountain (Ferguson et al., 1995), but the location and size of faults in this area are not well known.

The basement of the Española Basin is an eroded terrane of Eocene-Precambrian aged rocks uplifted during the Laramide mountain-building episode (orogeny, approximately 65 million years ago (m.y.a.). One of these uplifted areas, the Pajarito uplift, is bounded on the east by the Picuris-Pecos fault in the Sangre de Cristo Range and on the west by the Pajarito fault (Cather, 2004; Smith, 2004). At the time of Laramide uplift, the Pajarito fault was a westward-verging reverse fault, but it was reactivated as a down-to-the-east normal fault during Neogene (within the last 24 m.y.) subsidence of the Española Basin.

2.1.2.2. Structural Geology of the Pajarito Plateau

The Pajarito fault zone and its associated structures are the most prominent tectonic features of the LANL site (Figure 2-2). The fault, which forms a 120-m (400-ft) high escarpment on the western margin of the plateau, has the surface expression of a large, north-trending, faulted monocline. Along strike the fault varies from a simple normal fault to broad zones of small faults, faulted monoclines, and unfaulted monoclines. These varied styles of deformation are all considered expressions of deep-seated normal faulting. The amount of fault displacement for older rock units is not known because thick deposits of Bandelier Tuff cover critical relations. Stratigraphic separation on the Tshirege Member of the Bandelier Tuff (1.22 Ma) ranges between 80 and 120 m (260 to 400 ft) along the segment of the fault west of LANL (Gardner et al., 1999). Holocene movements (within the last 10,000 years) and historic seismicity indicate this fault system is still active.

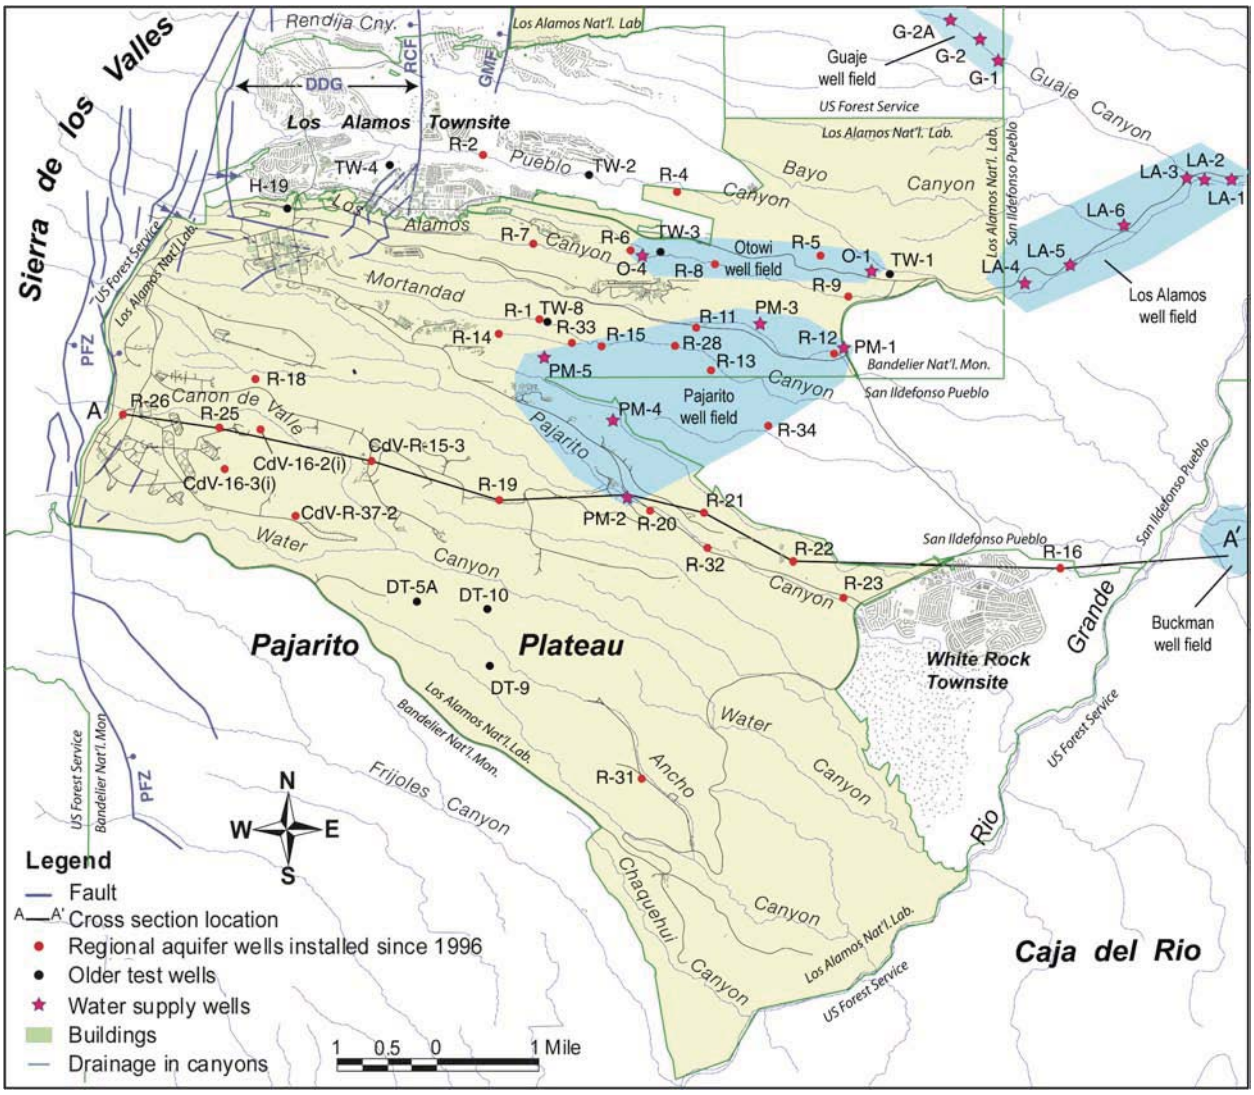

Figure 2-2. Location map of the central Pajarito Plateau.

Yellow-shaded area is the Los Alamos National Laboratory. Also shown are the municipalities of Los Alamos and White Rock. East- and southeast-trending canyons are incised into the plateau. Water supply wells are shown as blue stars and the water-supply well fields are indicated in blue shading; additional wells of Guaje well field extend north of this map. The Buckman well field provides water to Santa Fe. Water supply wells LA-1 through LA-6 are no longer used for municipal water production. New regional aquifer wells installed since 1998 are shown as red dots. Older test wells are shown as black dots. Line A-A' shows the location of the cross-section in Figure 2-5. Main elements of the Pajarito fault zone are shown in blue. PFZ is the main trace of the Pajarito fault zone; RCF is the Rendija Canyon fault; GMF is the Guaje Mountain fault; and DDG is the Diamond Drive graben. Faults modified from Gardner et al. (2001) and Lewis et al. (2002).

Other major faults on the Pajarito Plateau include the Rendija Canyon and Guaje Mountain faults. The Rendija Canyon fault, located in the northern part of the plateau, is a north-trending normal fault with down-to-the-west displacement. The Rendija Canyon fault dies out as a simple normal fault on the north side of LANL. Southward across LANL it is replaced by a broad arc of small-displacement faults that trend in a southwesterly direction towards the main trace of the Pajarito fault. The Guaje Mountain fault lies east of and is generally parallel to the Rendija Canyon fault. It is also a north-trending normal fault with down-to-the-west displacement. Surface traces of the Guaje Mountain fault die out north of LANL.

Additional faults are probably buried beneath the cover of Bandelier Tuff on the Pajarito Plateau. Where exposed along the east side of the basin, Santa Fe Group rocks are cut by numerous north-trending normal faults. Similar fault densities and orientations are probably present in the basin-fill sediments beneath the Pajarito Plateau. Unfortunately, existing well data are of limited use in defining these structures because of the complex depositional patterns and interfingering relations of Pre-Bandelier rock units beneath the plateau.

2.1.2.3 Volcanic Setting of the Pajarito Plateau

The Pajarito Plateau overlaps two volcanic fields whose activities were coeval with rifting. The plateau is bounded on the west by the Jemez volcanic field, a nearly circular volcanic field 72 km (45 mi) in diameter that includes the Valles caldera (Figure 2-1). The plateau is bounded on the southeast by the smaller Cerros del Rio volcanic field. The Jemez volcanic field was an important source of sediments during basin subsidence and the basin-fill sediments interfinger laterally with rocks of both volcanic fields.

Cerros del Rio Volcanic Field

The Cerros del Rio volcanic field is mainly exposed as the Caja del Rio basalt plateau on the east side of the Rio Grande. The surface of the basalt plateau ranges in elevation from 6000 to 7396 ft. The exposed part of the volcanic field extends about 26 mi in a north-south direction and is up to 12 mi wide. The volcanic field extends an additional 7 mi to the west beneath the Pajarito Plateau, where Bandelier Tuff covers it. The exposed portion of the volcanic field is made up of about a dozen volcanoes and >70 vents of cinder cones, plugs, and tuff rings. Basalts and related intermediate-composition lavas are the predominant rock types, and most were erupted between 2.3 and 2.8 Ma. The Rio Grande cuts a south-southwesterly course through the northwestern part of the basalt plateau, forming White Rock Canyon (Broxton and Vaniman 2005).

Jemez Volcanic Field

The Jemez volcanic field lies at the intersection of the northeast-trending Jemez lineament, a major crustal structure of Precambrian ancestry, and north-trending faults of the Rio Grande Rift. Volcanism over the last 14 million years (m.y.) built up the Jemez Mountains, while contemporaneous tectonic rifting resulted in subsidence of the Española Basin, the area extending from the Valles caldera to the western margin of the Sangre de Cristo Mountains. The Jemez volcanic highlands were a major source of Miocene and Pliocene volcaniclastic sediments that were deposited as alluvial fans in the western part of the Española Basin. Eastward, these volcaniclastic deposits interfinger with arkosic basin-fill sands and gravels derived predominantly from Precambrian–cored uplifts on the east side of the Española Basin.

The Jemez volcanic field began to develop between ~14 and 10 Ma with the eruption of predominantly basaltic and rhyolitic rocks of the Keres Group. Major rock units of the Keres Group include:

- **~14.5 to 7.6 Ma:** Basalts that were erupted predominantly in the southern and northeastern parts of the volcanic field.
- **~12.4 to 8.8 Ma:** The Canovas Canyon Rhyolite of the Keres Group, made up of rhyolite domes and associated pyroclastic deposits that were erupted from vents aligned along faults of the Cañada de Cochiti fault zone.
- **~10.6 to 7.1 Ma:** 1000 km^3 of andesite and subordinate basalt and rhyodacite that were erupted as part of the Paliza Canyon Formation.
- **7.1 to 6.0 Ma:** High-silica rhyolite plugs, domes, and tuffs of the Bearhead Rhyolite, including thick tuffaceous deposits of the Peralta Canyon Member, that were erupted from along faults of the Cañada de Cochiti fault zone.

The period from 6 to 7 Ma also coincided with a transition to predominantly dacitic volcanism throughout the volcanic field (Gardner et al., 1986). Porphyritc dacitic lavas of the Tschicoma Formation of the Polvadera Group were erupted primarily between 5 and 3 Ma (Goff and Gardner, 2004; G. WoldeGabriel, personal communication) from large, overlapping dome complexes typified by the extensive exposures of this formation in the highlands of the Sierra de los Valles west of the Pajarito fault zone.

Volcanism in the Jemez volcanic field reached a climax with eruption of the Bandelier Tuff from the Toledo and Valles calderas. The Bandelier Tuff has two members, each consisting of a basal pumice fall overlain by a petrologically related succession of ash-flow tuffs. Eruption of the two members was accompanied in each case by caldera collapse. The Otowi Member (1.61 Ma) was erupted from an earlier caldera that was nearly coincident with, and was largely destroyed by, the younger Valles caldera. The Valles caldera formed during the eruption of the Tshirege Member (1.22 Ma). About 300 km^3 of high-silica rhyolite magma was erupted for each of the two Bandelier Tuff members. Deposits of Bandelier Tuff form radially distributed flat-topped tuff plateaus that dip away from the central volcanic highlands. The Pajarito Plateau at LANL is made up of Bandelier Tuff that flowed more than 21 km across the western Española Basin.

An interval of about 400,000 years separated the eruptions of the two Bandelier Tuff members. During this interval, domes of Cerro Toledo Rhyolite were emplaced northeast and southeast of the earlier Toledo caldera. Tephras from these domes were deposited as ash and pumice falls over the Sierra de los Valles and Pajarito Plateau. The Cerro Toledo interval is a mixture of reworked Cerro Toledo Rhyolite tephras and Tschicoma dacite sediments eroded from the Sierra de los Valles.

2.2 Stratigraphic Framework of the Pajarito Plateau

A generalized diagram showing the stratigraphic sequence of rock units of the Pajarito Plateau is shown in Figure 2-3. Rock units are described below from oldest to youngest. The stratigraphy, lithology, and geochronology of the Santa Fe Group beneath the Pajarito Plateau are known primarily through drillhole data because Bandelier Tuff covers these older rock units. Based on

exposures near the Rio Grande and new drillhole data, the Santa Fe Group beneath the Pajarito Plateau is believed to include, in ascending order, the Tesuque Formation, older fanglomerate deposits of the Jemez volcanic field, the Totavi Lentil and older river gravels, pumice-rich volcaniclastic rocks, and the Puye Formation. Recent mapping of basin sediments north and east of Los Alamos suggests that the Tesuque Formation, as used in this report, may include rocks of the Chamita Formation (Koning et al., 2005). The older fanglomerate and pumice-rich volcaniclastic rocks are new units that are given provisional informal names. These units are generally similar to the Puye and Cochiti Formations, but are older than rocks normally assigned to them. Redefining the Puye and Cochiti Formations is beyond the scope of this report, and the older fanglomerates and pumice-rich volcaniclastic rocks are treated as informal units until they can be incorporated into the new stratigraphic framework being developed for the Española Basin (see discussion in Smith, 2004). In the vicinity of the Pajarito Plateau, Santa Fe Group deposits interfinger with or are overlain by volcanic rocks of the Jemez and Cerros del Rio volcanic fields. Rock units older than the Santa Fe Group (e.g., early Tertiary and older rocks) are not described here because they underlie the Laboratory at considerable depth and have not been penetrated by deep drillholes. These prebasin rock units are described in papers by Biehler et al. (1991), Cather (1992 and 2004), Ferguson et al. (1995), and Smith (2004).

The total thickness of the Santa Fe Group in the eastern and northern part of the Española Basin is as much as 1450 m (4800 ft) (Galusha and Blick, 1971). The Yates La Mesa no. 2 exploration well penetrated 1200 m (3966 ft) of Tesuque Formation in the south-central part of the basin (Meyer and Smith, 2004). However, the thickest Santa Fe Group deposits are believed to occur in the western Española Basin beneath the Pajarito Plateau (Kelly, 1978; Biehler et al., 1991; Ferguson et al., 1995; Smith, 2004). The thickness of these deposits is not well known because the deepest wells on the plateau (e.g., PM-5 with a depth 950 m; 3110 ft) do not fully penetrate the basin-fill sediments. Biehler et al. (1991) estimate that the Santa Fe Group in the central basin might be as much as 2000 m (6650 ft) thick based on gravity data. Cross sections by Kelly (1978) and Koning and Maldonado (2001) show up to 2750 to 3300 m (9000 to 10000 ft) of Santa Fe Group deposits in the central and western parts of the basin. Drillhole data and outcrops indicate that Santa Fe Group deposits are considerably thinner (<500 m; <1640 ft) west of the Pajarito fault (Goff and Gardner, 2004).

This section includes structure contour maps (contoured elevations at the top or bottom of a hydrogeologic unit) and isopach maps (contoured maps showing the unit thickness). These maps, which are prepared by interpolation between points of one-dimensional drillhole data, provide information on the extent of a unit beneath the site and the relative contribution of each unit to the hydrostratigraphy at any given point. Isopach and structure-contour figures representing key hydrostratigraphic units include:

- Cerro Toledo interval (Figure 2-4),
- Otowi Member ash flows (Figure 2-5),
- Guaje Pumice Bed at the base of the Otowi Member (Figure 2-6),
- Cerros del Rio lavas (Figures 2-7 and 2-8),
- Pumiceous volcaniclastic rocks (Figure 2-9).

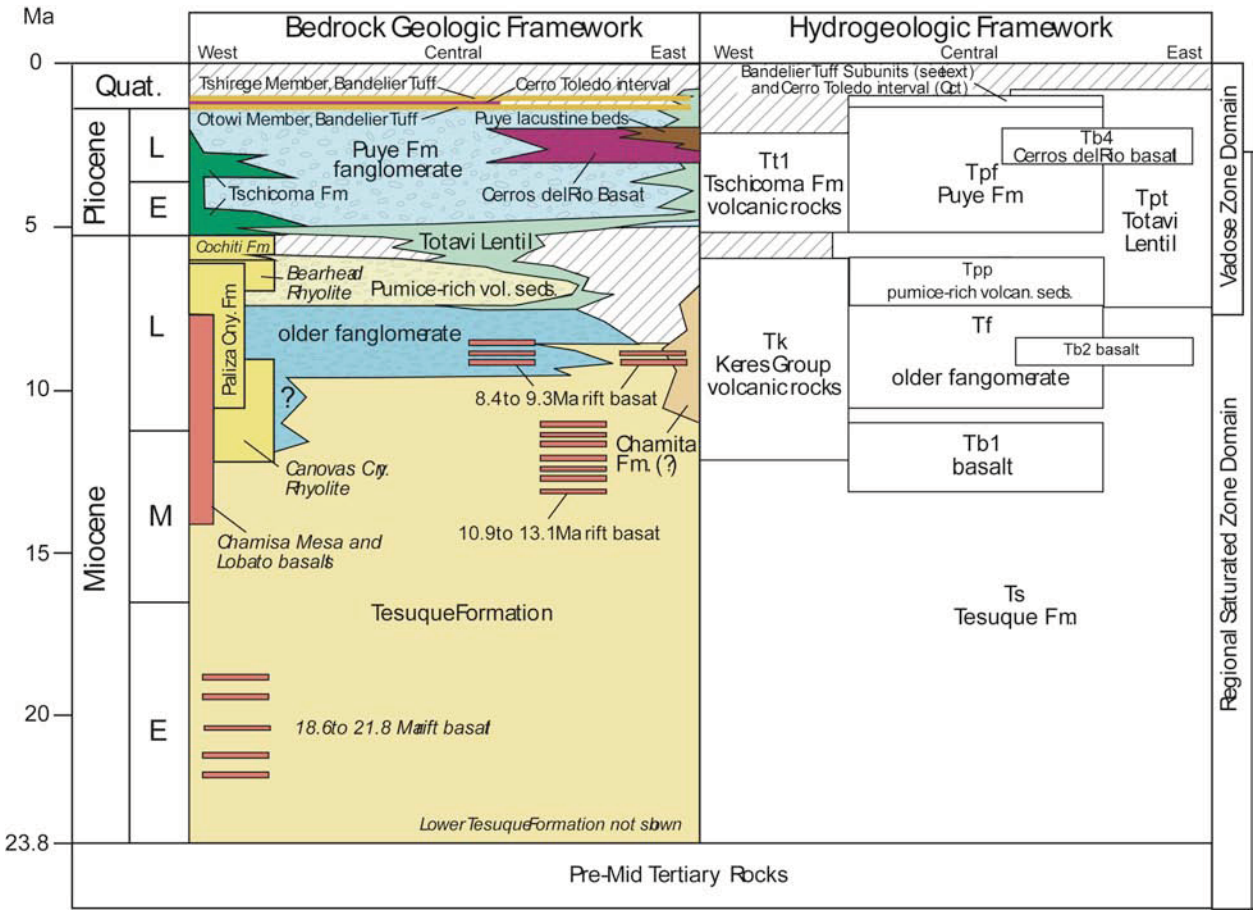

Figure 2-3. Pajarito Plateau stratigraphy and hydrogeologic units as used in this report. The bedrock geologic framework shows the stratigraphy of the plateau and the adjacent Sierra de los Valles. Units with italicized names are not exposed or penetrated by boreholes in the immediate vicinity of the plateau, but they are coeval units of the Jemez volcanic field that may be important source rocks for plateau deposits. The hydrogeologic framework shows units that are defined for site-wide numerical modeling (Broxton and Vaniman, 2005).

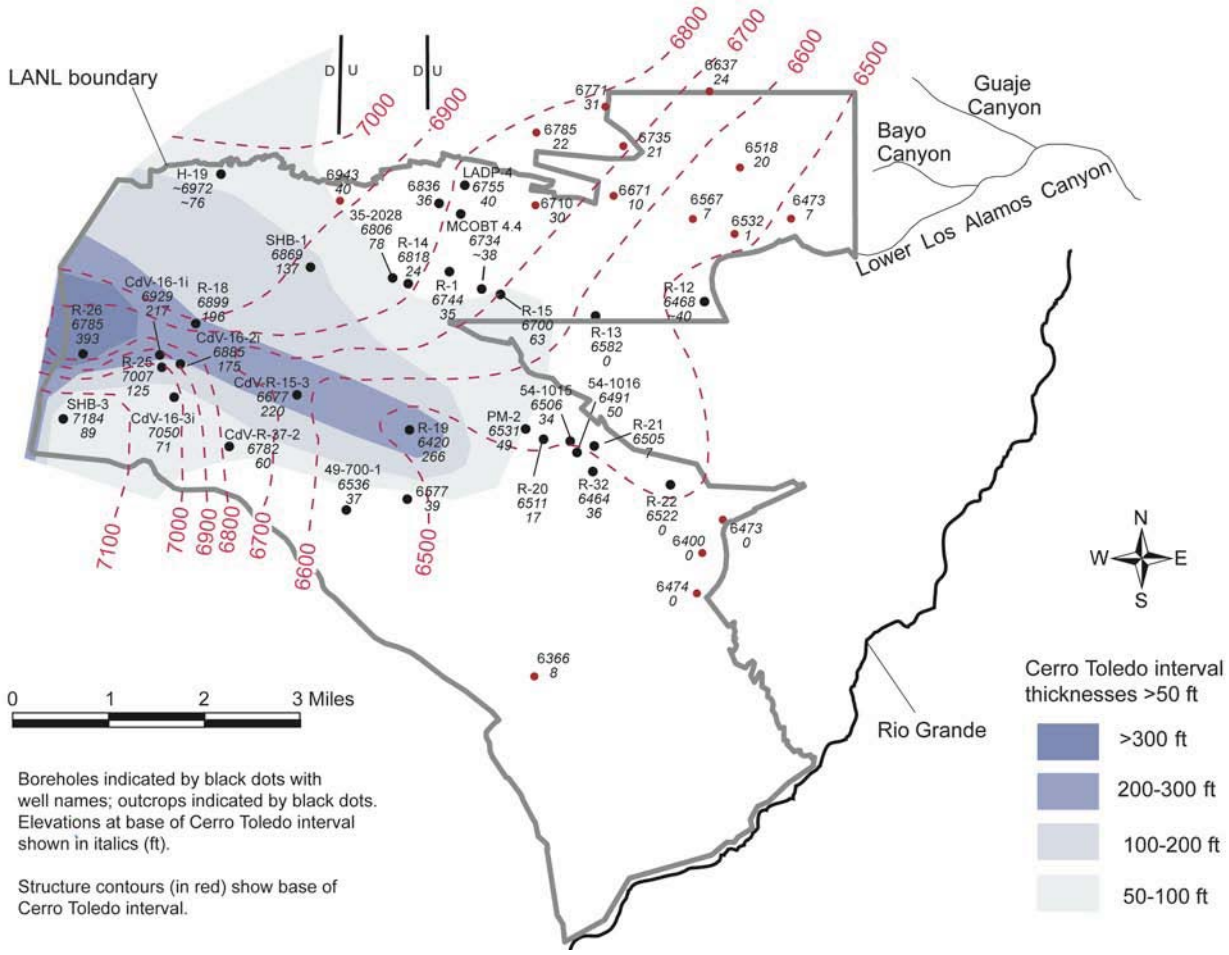

Figure 2-4. Structure contour and isopach map for the Cerro Toledo interval. Structure contours for base of unit indicate that Cerro Toledo filled a broad southeast-trending paleovalley incised into the Otowi Member (see isopach map for Otowi Member in Figure 2-5). The thickest Cerro Toledo deposits coincide with the axis of the paleovalley.

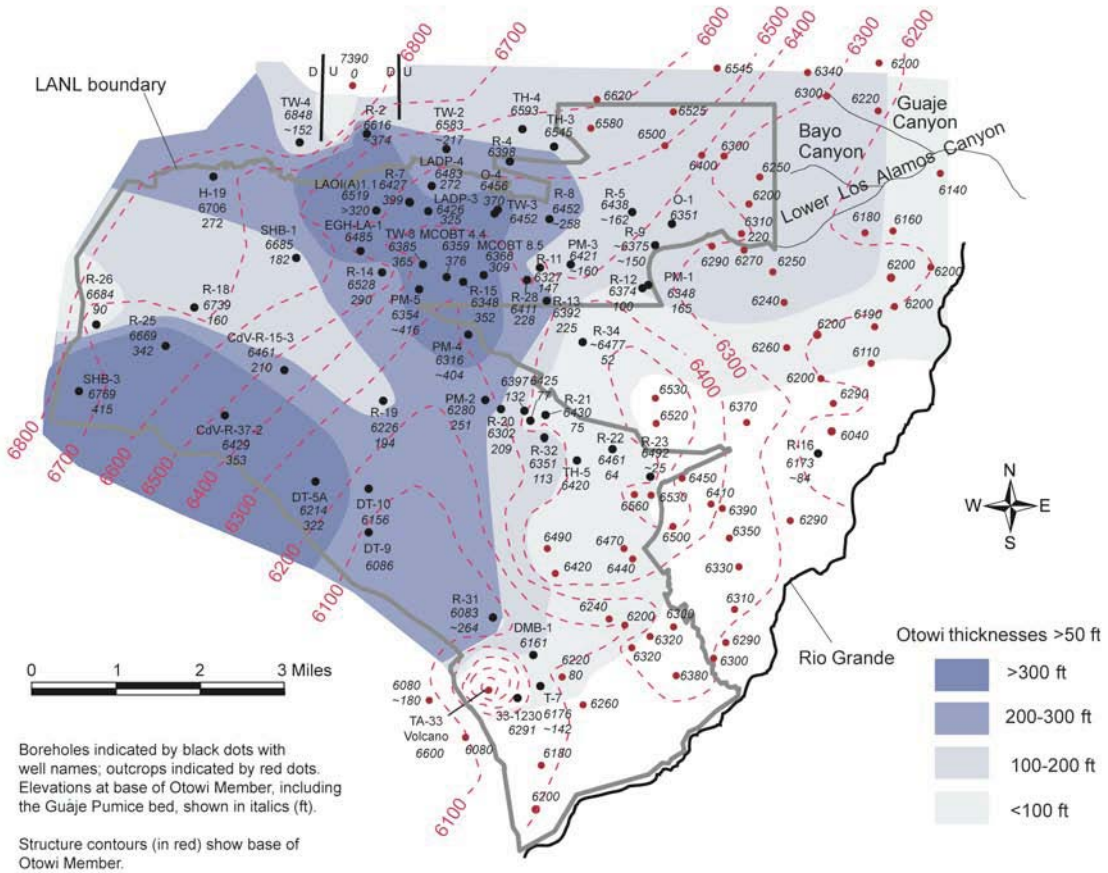

Figure 2-5. Structure contour and isopach map for the Otowi Member of the Bandelier Tuff. Structure contours are for base of Guaje Pumice Bed and show the paleotopography prior to eruption of the Otowi Member. Otowi ash-flow tuffs filled a broad north-trending paleovalley bounded by the Sierra de los Valles highlands on the west and the Cerros del Rio basaltic highland on the east. The variable thickness of the Otowi Member on the western side of the plateau represents deep erosion of these poorly consolidated nonwelded tuffs prior to eruption of the Tshirege Member.

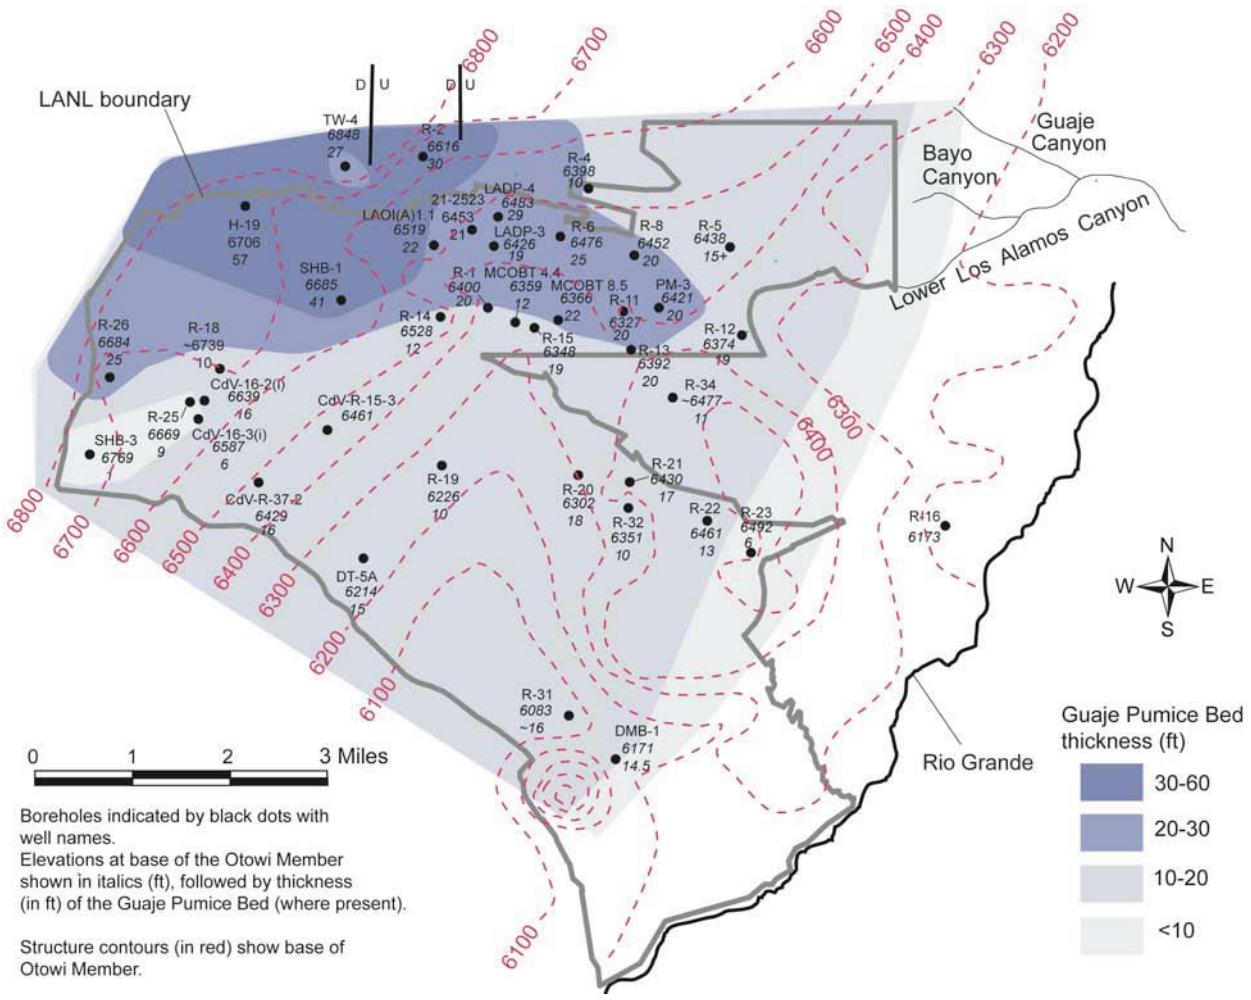

Figure 2-6. Isopach and structure contour map of the Guaje Pumice Bed.

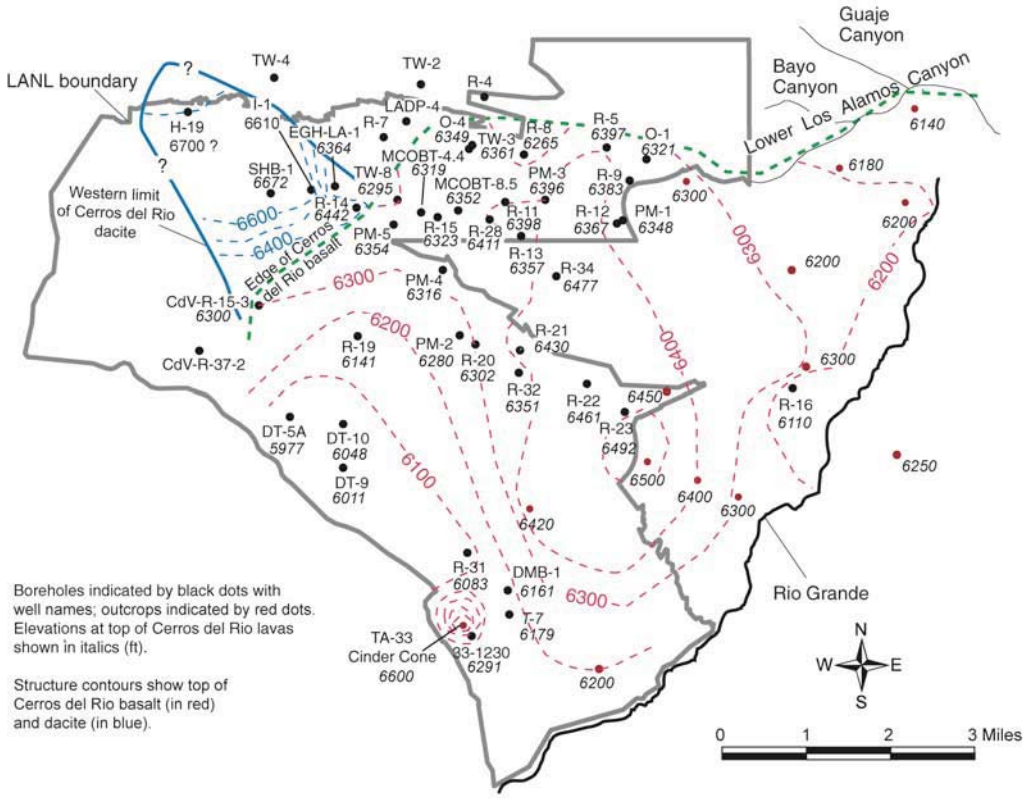

Figure 2-7. Structure contour for the top of Cerros del Rio basalt and western dacite on the Pajarito Plateau. Green dashed line indicates the northern and western extent of the Cerros del Rio volcanic field. Blue line indicates western extent of dacitic lavas that were contemporaneous with the basalts. Top of Cerros del Rio basalts formed broad north-trending highland on east side of plateau. This highland is now covered by Bandelier Tuff.

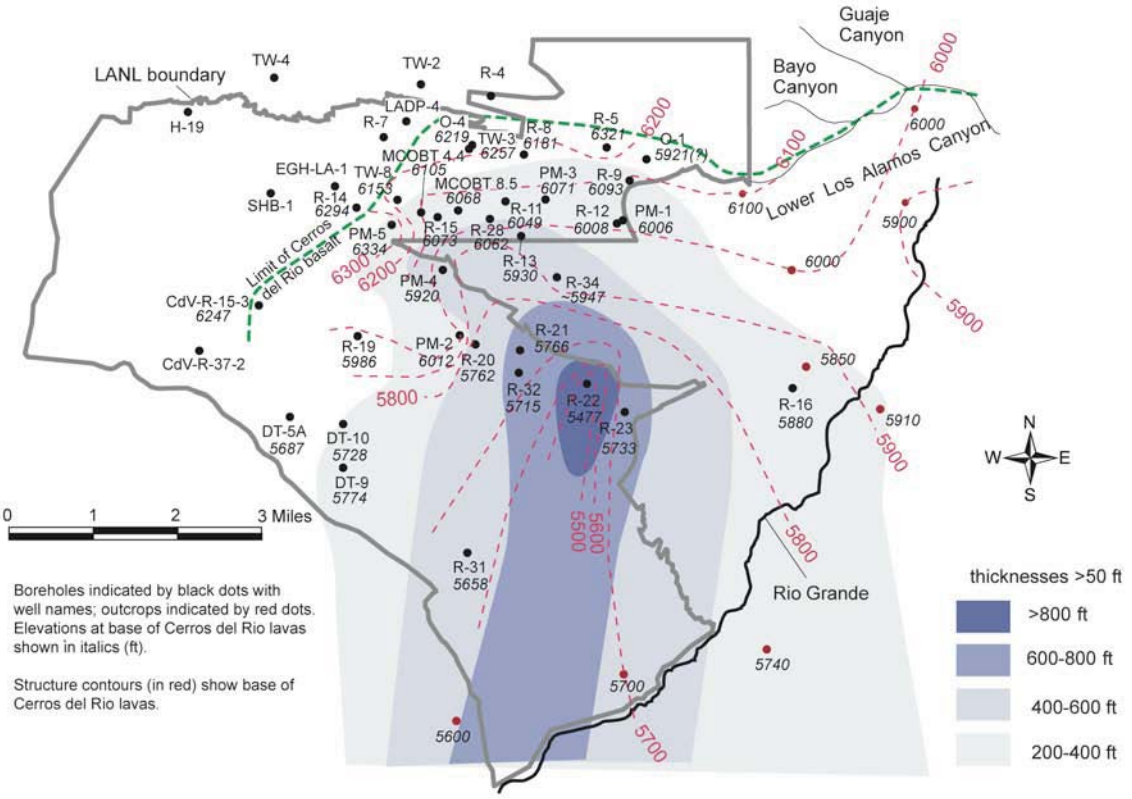

Figure 2-8. Structure contour for the base of Cerros del Rio basalt with isopachs showing the cumulative thickness of flows. Green dashed line indicates the northern and western boundary of the Cerros del Rio volcanic field. The maximum thickness of basalt corresponds with structural-contour lows, suggesting that the basalts accumulated in topographic basins.

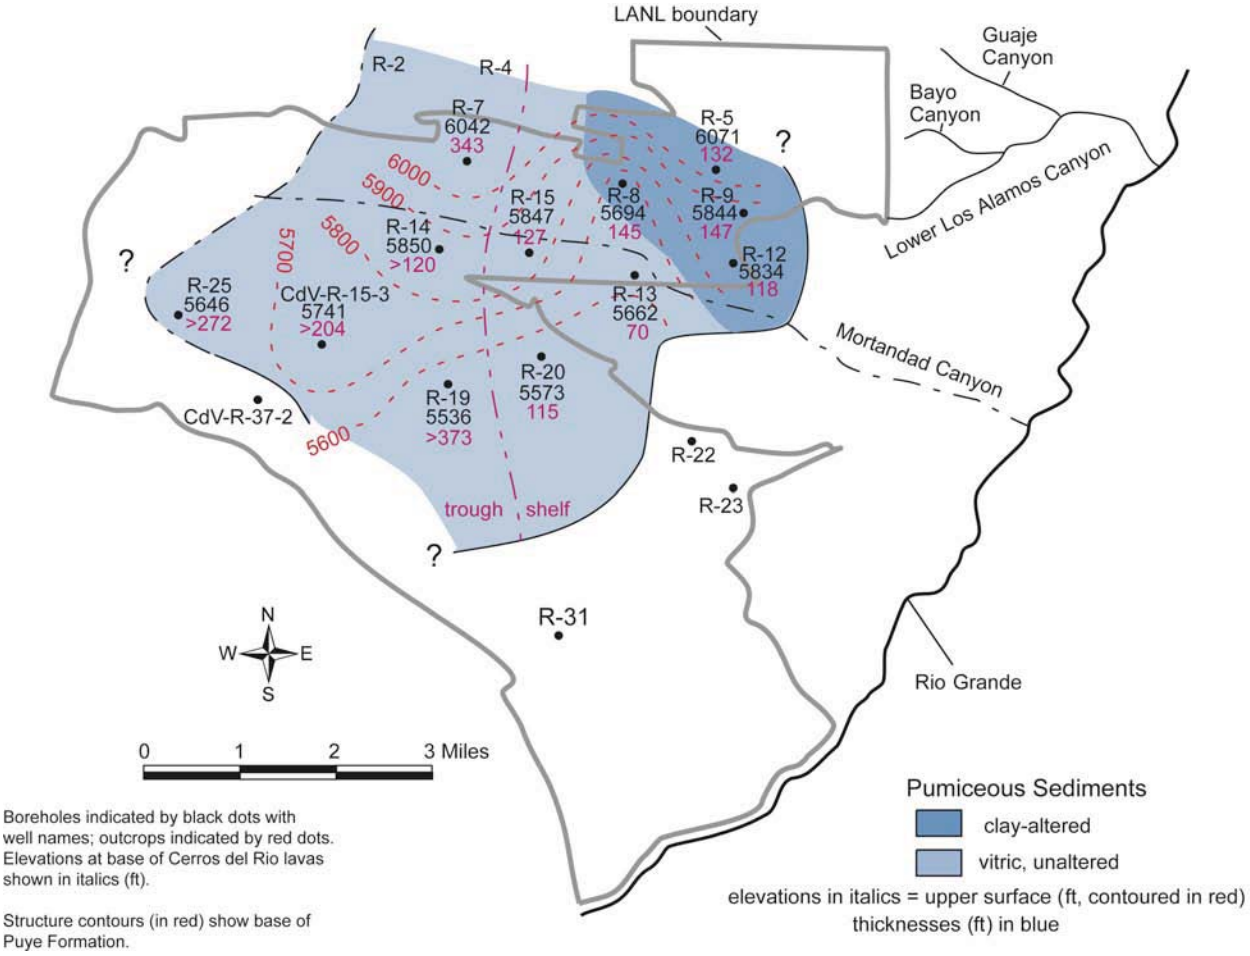

Figure 2-9. Topography at the upper surface of the pumiceous deposits underlying Puye Formation fanglomerates, with pumiceous deposit thicknesses (ft) indicated in blue. Color shading is used to distinguish vitric unaltered pumiceous deposits from those that are clay-altered.

Each of these figures is based on the interpretations of cuttings, geophysical logs, and in some cases borehole video data to determine the elevations of the upper and lower stratigraphic contacts for individual stratigraphic units. Isopach maps for shallow units that crop out in canyon walls, such as the Cerro Toledo interval and the Otowi Member, are corrected for the effects of the modern canyon incision. Each point on the figure represents either a borehole (with borehole name listed) or an outcrop location (without a borehole label). The data points list the elevation of the basal contact in ft above sea level (asl) and the unit thickness in ft. Dashed red contours are hand-generated and indicate an interpretation of the topology of the geologic contact; increasingly darker shades of blue indicate increasing unit thickness above this topologic surface.

2.2.1 Tesuque Formation

The Miocene Tesuque Formation is partially penetrated by wells in the eastern part of the Pajarito Plateau where it makes up a significant portion of the aquifer for local communities and LANL (Purtymun, 1995). It is primarily made up of thick fluvial deposits consisting of partly lithified, arkosic sediments derived from Precambrian granite, pegmatite, and sparse sedimentary rocks of the Sangre de Cristo Range and from Tertiary intermediate to felsic volcanic rocks from northern New Mexico and possibly southern Colorado (Cavazza, 1989). Individual beds are generally less than 3 m (10 ft) thick and consist of massive to planar- and cross-bedded light pink-to-buff siltstone and sandstone, with minor lenses of pebbly conglomerate. Exposures near the Rio Grande (Koning and Maldonado, 2001) indicate that the Tesuque Formation beneath the plateau probably consists primarily of the Pojoaque Member. In well PM-5, a 110-m (360-ft) thick series of basalt flows within the Tesuque Formation yielded a $^{40}Ar/^{39}Ar$ date of 11.39 ± 0.40 Ma (WoldeGabriel et al., 2001).

Based on Formation Microimager (FMI) logs for well R-16, bedding in the Tesuque Formation on the east side of the plateau dips predominantly towards the west-northwest (LANL, 2003). The mean dip is 11° but dips tend to be greater in the lower part of the well (median dip 14° below 1170 ft) than in the upper part (median dip 9°). Tesuque beds just east of the Rio Grande dip westward mainly at angles of 3° to 10° (Koning and Maldonado, 2001).

2.2.2 Miocene Basalts

Miocene basalts are intercalated with Santa Fe Group deposits in the east-central part of the Pajarito Plateau. WoldeGabriel et al. (1996) divided these basalts into two age groups based on $^{40}Ar/^{39}Ar$ dates. The older group ranges in age from 10.9 to 13.1 Ma and is largely found in the vicinity of Guaje Canyon. The younger group ranges in age from 8.4 to 9.3 Ma and is found over a wide area that extends from Bayo Canyon on the north to Ancho Canyon on the south and from PM-1 on the east to PM-5 to the west.

2.2.3 Older Fanglomerate

The informal term “older fanglomerates” refers to a thick sequence of late Miocene fan deposits that were shed from the Jemez volcanic field into the western Española Basin. These deposits, which are found only in deep boreholes, are important for the development of high-yield,

low-draw-down municipal and industrial water supply wells on the Pajarito Plateau (Purtymun, 1995). Purtymun (1995) called these deposits the "Chaquehui Formation" and assigned them a post-Chamita and pre-Puye age. From borehole observations, the Chaquehui Formation consisted of up to 1500 ft of gravels, cobbles, and boulders derived from the Jemez volcanic field and volcanic, metamorphic, and sedimentary rocks derived from highlands to the north and east. However, the Miocene deposits identified as Chaquehui Formation in deep wells are more appropriately called "older fanglomerates" because recent stratigraphic studies indicate the Chaquehui Formation type section consists of younger (late Pliocene) phreatomagmatic deposits (Heiken et al., 1996).

The older fanglomerates are widespread beneath the Pajarito Plateau, based on borehole observations. These deposits are mostly made up of volcanic detritus derived from Keres Group rocks and possibly from early Tschicoma Formation centers. They are characterized by dark, lithic sandstones and gravel and cobble deposits dominated by fresh to silicified, subangular to rounded andesite, latite, and porphyritic dacite. Subordinate clasts (<10%) include subangular to rounded rhyolite and basalt, and rounded quartzite. Rounded granite and angular chert clasts are generally rare (<1%) (Broxton and Vaniman 2005).

Precambrian quartzite, granite, and chert clasts are persistent, but in low abundance in the older fanglomerates. The source of Precambrian clasts may be Santa Fe Group rocks that were exposed within the Jemez volcanic field at the time of Keres volcanism. Stratigraphic relationships described by Gardner and Goff (1996) indicate that Santa Fe Group deposition interfingered with Keres volcanism in the caldera area. Additionally, rounded quartzite and granitic gneiss pebbles are found in lag gravels on the resurgent dome of the Valles caldera where they presumably weathered out of Santa Fe Group rocks in megabreccia blocks that slumped into caldera during caldera collapse (Goff et al., 2003).

The maximum thickness of older fanglomerate penetrated by wells is 1650 ft in well Otowi-4. However, thicknesses could be greater to the west where drillholes did not fully penetrate the unit. The westward thickening wedge of volcaniclastic sedimentary deposits corresponds to the zone of thick, highly productive aquifer rocks that extend northeastward across the central plateau as described by Purtymun (1995). The western boundary of this thick sequence of sediments is poorly defined, but recent drilling results suggest that these rocks probably extend to the Pajarito fault zone. The older volcaniclastic deposits abruptly thin eastward between east-west pairs of wells such as R-23/R-22 and Otowi-1/Otowi-4. The transition zone generally corresponds to the eastern boundary of the gravity low beneath the Pajarito Plateau described by Ferguson et al. (1995).

2.2.4 Totavi Lentil

The Totavi Lentil is made up of river-channel sands and gravels that crop out along the Puye escarpment, in lower Los Alamos and Guaje Canyons, and along White Rock Canyon. These rocks are also penetrated by a number of wells on the Pajarito Plateau. These axial-channel deposits were named the Totavi Lentil of the Puye Formation for a type section in Los Alamos Canyon (Griggs, 1964). Griggs recognized their importance as ancestral Rio Grande deposits,

and he used them to delineate the base of the Puye Formation with which they are conformable in outcrops.

The Totavi Lentil is a poorly consolidated conglomerate containing well-rounded cobbles and gravels of Precambrian quartzite, granite, and pegmatite with subrounded to subangular cobbles and boulders of silicic to intermediate and rarer basaltic volcanic rocks. Precambrian clasts typically make up >80% of the clasts in the deposits. Though commonly subordinate in abundance, clasts of volcanic rocks from the Jemez volcanic field make up to 50% of the deposit in some interbedded horizons. Lenses of loose, well sorted, fine to coarse sands containing abundant quartz and microcline are intercalated with the conglomerate. Totavi deposits are generally ~50 ft thick near the Rio Grande and thicken to the northwest (Griggs, 1964). An unusually thick sequence of quartzite-rich conglomerate (>323 ft) was penetrated in well R-31, located in Ancho Canyon. A number of wells (e.g. R-5, R-9, R-12, R-32) did not encounter the Totavi Lentil, indicating that these channel conglomerates may form lenticular deposits of limited lateral extent.

Based on new well data, it is evident that ancient river deposits in the Pajarito Plateau area are coeval with variety of stratigraphic units that span a longer time interval than previously recognized. River gravels occur beneath the pumice-rich volcaniclastic rocks (described below) in wells R-13, R-15, R-20, R-33, R-34, PM-1, PM-2, and PM-5. These river gravel deposits are generally 10- to 30-m (30- to 100-ft) thick and include abundant well-rounded gravels of quartzite, angular to subangular basalt, andesite, and dacite, and minor metavolcanics. Granitic clasts are rare to absent. Radiometric ages indicate the overlying pumice-rich volcaniclastic rocks are late Miocene in age. In well H-19, river gravels 3-m (10-ft) thick occur as rounded quartzite pebbles between two Tschicoma lava flows (Griggs, 1955, 1964). The quartzite-dominated clast compositions suggest these gravels were derived from the Tusas Mountains and were transported southward by the ancestral Rio Chama, with tributaries draining the Jemez volcanic field. A late Miocene age for the early riverine deposits is consistent with geologic interpretations that through-going rivers were established in the Española Basin prior to about 6.96 Ma (Smith et al., 2001; Smith, 2004).

2.2.5 Pumice-Rich Volcaniclastic Rocks

The pumice-rich volcaniclastic rocks (pumiceous deposits) are characterized by well-bedded horizons of light-colored, reworked, tephra-rich sedimentary deposits and subordinate primary ash- and pumice-fall deposits. These rocks consist mainly of tuffaceous sandstones and contain a few beds of lava-rich gravels. The underlying older fanglomerate and overlying Puye Formation contain higher percentages of gravel and cobble beds. In a number of wells, pumice-rich volcaniclastic rocks are separated from the older fanglomerate by the Totavi Lentil (axial deposits of the ancestral Rio Grande).

The pumice-rich deposits typically contain 10 to 30% subangular to rounded, rhyolitic lapilli mixed with 70 to 90% ash and lithic sands. Gravels contain porphyritic dacite, rhyolite, and lesser andesite and basalt. Some intervals contain as much as 90% subangular to angular pumice lapilli that represent primary fall deposits or reworked deposits that underwent minimal transport. In most areas, pumice lapilli are vitric and show little effect from submergence within

the regional saturated zone except for oxidation on clast surfaces and minor clay development in vesicles.

However, these deposits are diagenetically altered where most of the volcanic glass is replaced by smectite in the northeastern portion of the Laboratory, an area defined by wells R-5, R-8, R-9, and R-12. Shadings of blue in Figure 2-9 distinguish vitric unaltered pumiceous deposits (pale blue) from those that are heavily clay-altered and retain little or no glass (dark blue). The formation of clay in this area is locally accompanied by abundant calcite and variable amounts of zeolite alteration. Because of the extent of alteration, the lack of preservation of glass, and the loss of many petrographic clues for individual pumice bed correlation, it is difficult to determine whether the heavily altered pumices are related to the unaltered pumice or represent an earlier pumice unit and an earlier alteration event.

Most lapilli in the pumice-rich volcaniclastic rocks are aphyric or contain sparse phenocrysts of quartz, sanidine, and plagioclase, but the presence of some biotite-, hornblende-, and pyroxene-phyric varieties indicates that multiple volcanic sources supplied tephra to these deposits. Seven recent $^{40}Ar/^{39}Ar$ feldspar ages between 6.8 and 7.5 Ma were obtained from crystal-poor pumice falls in six wells that penetrate into this unit. The younger ages overlap the 6.01 to 7.1 Ma range of ages reported for the Bearhead Rhyolite (Justet, 1996; Smith, 2001) and the older ages are slightly older. Additional work is taking place to investigate the relation between the pumice-rich volcaniclastic rocks and Keres Group silicic volcanism with the goal of assigning the pumiceous sediments to either the Puye or Cochiti Formations or delineating them as a separate formation.

The pumice-rich volcaniclastic rocks thin northeastward across the central part of the plateau and are absent north of Pueblo Canyon. Borehole geophysical logs indicate that these deposits dip 5° to 15°, primarily towards the southwest and west. Figure 2-9 illustrates structure contours and thickness of pumiceous deposits that occur over a broad region beneath the central portion of the Laboratory where multiple pumice beds have been encountered. Observations from boreholes suggest that the structure of these pumiceous deposits is complex, including both primary and reworked pumiceous units intermixed with fanglomerates. Nevertheless, the pumiceous unit is predictably encountered in the area shown in Figure 2-9. Drilling experience shows that this unit is highly transmissive, providing a difficult drilling horizon where injected fluids are likely to be lost. Hydrologic testing shows that the pumiceous deposits have relatively high transmissivity (Section 2.3.4.2).

In Figure 2-9 the structure contours represent the top, rather than the bottom of the pumiceous deposits. This is done because the bottom of this unit is poorly constrained in R-series drillholes to the south and west, where this unit was seldom penetrated. The structure contours at the top of the pumiceous unit show that it slopes to the south and shows evidence of incision of a broad south-trending paleocanyon, filled by Puye fanglomerate, in the central portion of the Laboratory. This broad canyon is somewhat similar to that seen at the base of the Bandelier Tuff (Figure 2-6) and at the base of the Cerros del Rio volcanic rocks (Figure 2-8), suggesting that broadly south-trending canyons have been a common feature for over 5 m.y. prior to the eruption of the Bandelier Tuff. The present west-northwest/east-southeast drainages on the plateau may be a relatively recent drainage pattern that developed on the thick east-sloping tuff ash flows emplaced after 1.6 Ma.

2.2.6 Tschicoma Formation

The Tschicoma Formation of the Polvadera Group consists of thick, predominantly dacite to low-silica rhyolite lava flows erupted from large overlapping dome complexes. Major peaks in the Sierra de los Valles, including Cerro Grande, Pajarito Mountain, Caballo Mountain, and Tschicoma Mountain, are compositionally distinct lava domes that represent separate volcanic source areas for detritus that was shed to form the Puye fanglomerates. Low-silica rhyolite erupted from a deeply eroded dome complex in the upper Rendija Canyon and Guaje Mountain area yielded three ages between 4.95 and 5.32 Ma. Dacites of the Cerro Grande, Pajarito Mountain, and Caballo Mountain centers have closely overlapping ages of 2.91 Ma to 3.34 Ma (Broxton and Vaniman, 2005).

Outcrops of the Tschicoma Formation in the Sierra de los Valles are primarily gray to purplish-gray lavas characterized by pronounced jointing and flow foliation. The interflow zones between flow units are commonly marked by blocky breccias. Flow interiors consist of dense, massive rock that is commonly devitrified to form a microcrystalline groundmass, giving the rocks a stony appearance. Chilled volcanic glass is sometimes preserved in flow tops and bottoms. Fragmental deposits of ash and lava debris occur in the distal parts of the formation.

The Tschicoma Formation is at least 2,500 ft thick in the Sierra de los Valles, but has a variable thickness due to the lenticular shapes of its lava flows. The Tschicoma Formation thins eastward under the western Pajarito Plateau where it interfingers with the Puye Formation. The Tschicoma Formation was encountered in wells TW-4, H-19, CDV-16-3(i) and CDV-R-37-2 in the western part of the Pajarito Plateau, but is absent in boreholes to the east, with the possible exception of thick dacite lava in boreholes EGH-LA-1, SHB-1, and I-1. These lavas may be assigned to the Tschicoma but their source and distribution is presently unknown.

2.2.7 Puye Formation

The Puye Formation is a large apron of overlapping alluvial and pyroclastic fans that were shed eastward from the Jemez volcanic field into the western Española Basin (Griggs, 1964; Turbeville et al., 1989). The Puye Formation unconformably overlies rocks of the Santa Fe Group (Tesuque Formation), and the Otowi Member of the Bandelier Tuff unconformably overlies it. Turbeville et al. (1989) estimated its areal distribution at 200 mi^2 and its volume at ~3.6 mi^3. Because its primary source area was volcanic domes in the Sierra de los Valles, the Puye Formation overlaps and post-dates the Tschicoma Formation in age. The Puye Formation is subdivided into fanglomerate and lacustrine facies.

The fanglomerate facies, the dominant unit of the Puye Formation, is a heterogeneous assemblage of clast- to matrix-supported conglomerates, and of gravels and lithic-rich sandstones. Clasts in the coarsest deposits consist of subangular to subrounded cobbles and boulders of latite, dacite, rhyolite, and tuff in a poorly sorted matrix of ash, silts, and sands. Consolidated mudflow deposits are common throughout the unit, and tend to be cliff-forming. At least 25 ash beds of dacitic to rhyolitic composition are interbedded with the conglomerates and gravels (Turbeville et al., 1989).

The lacustrine facies includes lake and riverine deposits in the upper part of the Puye Formation. These deposits are characterized by lacustrine fine sand, silt, and clay up to 30 ft thick. Basaltic ash beds (maar deposits) up to 10 ft thick are locally present above or below the lacustrine deposits. The lacustrine facies includes some well-rounded riverine gravels of Precambrian quartzite and gneiss that fill channels cut into the underlying fanglomerates. The lacustrine facies crops out in lower Los Alamos Canyon and extends both northward and southward in discontinuous outcrops for several miles. Apparently, their extent is limited to the eastern side of the plateau because they are found only in wells R-9, R-12, and R-16. Because of their spatial and temporal association with palagonitic basalt flows and maar deposits, these lacustrine deposits probably represent periods of damming and diversion of the Rio Grande caused by the eruptions of lavas within the Cerros del Rio volcanic field.

The Puye Formation reaches a maximum thickness of >1000 ft in well R-25 on the western side of the Laboratory but thins to 50 ft in areas north of the Pajarito Plateau. In the central and eastern portions of LANL, it is about 600 ft thick and the upper Puye is interbedded with basaltic lavas of the Cerros del Rio volcanic field.

2.2.8 Basaltic Rocks of the Cerros del Rio Volcanic Field

Cerros del Rio basalts typically form thick sequences of stacked lava flows separated by interflow breccia, scoria, sediment, and ash. These rocks are mostly basalts and basaltic andesites, but subordinate dacite is present within thick basalt stacks in the east and central plateau (e.g. Ball et al., 2002) or is found as isolated flows on the western side of the volcanic field. Cerros del Rio lavas were erupted from vents located both east and west of the Rio Grande (Smith et al., 1970; Aubele, 1978; Kelley, 1978).

In major-element composition the dacitic components are very similar to partially contemporaneous dacitic lavas that occur within the highlands of the Tschicoma Formation to the west. However, dacites are less abundant than basalts within the Cerros del Rio and these thin dacitic lavas have relatively few of the common hydrous minerals (amphibole and biotite) that characterize most of the Tschicoma lavas. These distinctions are important because they strongly affect the hydrogeologic character of the lavas. Lavas of the Cerros del Rio lie within suites of relatively thin (a few tens of feet), largely basaltic lava flows with laterally extensive flow-boundary rubble zones that provide pathways for flow. Lavas of the Tschicoma Formation are far more massive, up to hundreds of feet thick, and are generally poorly transmissive (Griggs, 1964).

Individual flows typically range in thickness from about 3 ft to more than 100 ft. The internal structures of flows show some similarities to those described for the Columbia River Basalt Group in Washington, Oregon, and Idaho and for Snake River basalts in Idaho (Swanson et al., 1979; Whiteman et al., 1994; Faybishenko et al., 2000). In ascending order, the flows are characterized by: (1) a flow base characterized by vesicular basalt with clinker and scoria, (2) a colonnade zone made up of vertical, large-diameter columns bound by cooling joints, (3) a thin zone of complexly-overlapping fractures, and (4) a flow top of vesicular basalt with scoria and clinker. In addition to highly porous clinker zones associated with flow tops and bottoms, interflow zones include cinder deposits and sedimentary deposits. Interflow cinder deposits are

fairly common, and their thickness is highly variable (0 to 100 ft), depending on proximity to source vents. The thickest cinder deposits are as much as 300 ft thick on or near source vents (e.g. R-34). Interflow sedimentary deposits are generally thin (<20 ft) where present and consist mostly of reworked basaltic rocks. In the eastern part of the plateau, where the basalts interacted with surface water, flow bases commonly include porous, pillow-palagonite complexes.

The basaltic rocks of the Cerros del Rio volcanic field include buried remnants of maar volcanoes in White Rock Canyon. The aprons of fragmental debris surrounding these buried craters consist of thin layers of basaltic ash and sediments. The maar deposits resulted from steam explosions that occurred where basalt erupted through an aquifer or standing body of water. Thin maar deposits were identified at the base of the Cerros del Rio basalt in R-9 and R-12.

The distribution, form, and thickness of the Cerros del Rio volcanic field beneath the plateau are illustrated in Figure 2-7, which shows the topography at the top of the Cerros del Rio and Figure 2-8, which shows structure contours (red dashed lines) at the base of the Cerros del Rio. In Figure 2-8 shadings of purple represent the variation in thickness of the total Cerros del Rio deposits that lie between the two contoured surfaces in these figures.

Figure 2-7 shows that the upper surface of the Cerros del Rio is irregular, with a broad highland that extends from north to south under the east-central portion of the Laboratory. This highland is largely buried beneath the Bandelier Tuff, but remnants of the eastern slope extending from the highland are exposed beneath the town of White Rock. The highland represents distributed volcanic centers that produced most of the basaltic and dacitic lavas that underlie the Laboratory. Direct evidence of these eruptive centers is found in thick cinder deposits that were encountered in drillholes R-22 and especially R-34, and a low cinder-covered volcanic center exposed just south of R-23 in TA-36. These cinder deposits are extremely porous and generally provide highly transmissive media, but they are localized around volcanic centers so that enhanced groundwater flow is likely to extend for less than one mile, based on the extent of the TA-33 cinder cone (Figure 2-7).

Figure 2-8 shows the topography at the base of the Cerros del Rio volcanic series and the exceptional thickening of these deposits beneath R-22 and (probably) extending along a paleocanyon extending to the south. The extent of this deep trough to the north and south is not well defined by current drillhole locations. Based on the absence of Totavi-like deposits within this channel at R-22 and the lack of evidence to the northeast in the canyon walls of lower Los Alamos Canyon, it is likely that the head of the canyon rose steeply to the northwest and drained the Sierra de los Valles. This thick keel of lavas and intercalated rubble zones occurs largely beneath the regional aquifer water table and hosts an important part of the regional aquifer beneath the southeast portion of the Laboratory. It is possible that this feature could affect the flow direction and head distributions at depth.

2.2.9 Bandelier Tuff

The Laboratory facilities are located almost entirely on mesa and canyon outcrops of Bandelier Tuff. The Bandelier Tuff consists of ash flows and minor airfall pyroclastic deposits with ages of

1.61 Ma for the Otowi Member and 1.22 Ma for the Tshirege Member (Izett and Obradovich, 1994). The two Bandelier Tuff members are separated by the Cerro Toledo interval, which is a stratified sequence of volcaniclastic sediments and tephra of mixed provenance. Although it occurs between the ash-flow members of the Bandelier Tuff, the Cerro Toledo interval is not considered part of the Bandelier Tuff, a usage consistent with the original definition by Bailey et al. (1969).

2.2.9.1 Otowi Member, Bandelier Tuff

The Otowi Member crops out in several canyons but is best exposed in Los Alamos Canyon and in canyons to the north. It consists of moderately consolidated, porous, nonwelded ash-flow tuffs that form colluvium-covered slopes along the base of canyon walls. The Otowi ash-flow tuffs are vitric and contain light gray-to-orange pumice supported in a white to tan ashy matrix of glass shards, broken pumice, crystals, and rock fragments. The Otowi Member is made up of multiple ash flows, but individual ash-flow deposits cannot be traced in the subsurface using core and cuttings from widely spaced boreholes. The base of the member is called the Guaje Pumice Bed (Figure 2-6), and is discussed below. In some drillholes, a shift in borehole gamma measurements in the central part of the unit provides a useful datum for correlations between drillholes. The nonwelded ash-flow tuffs of the Otowi Member collectively form a relatively homogenous rock unit throughout the plateau. Transport through this hydrogeologic unit appears to occur primarily by matrix flow, although open fractures may contribute to transport locally (e.g., R-25). Although made up of multiple flow units, the combined Otowi ash flows are massive, and borehole geophysical logs show only minor variations in density and porosity.

The present maximum thickness of Otowi Member occurs in two areas in the western part of the plateau where the deposits are about 350 to 400 ft thick. Otowi deposits are only <100 to 300 ft thick between these two areas. The thin deposits are overlain by unusually thick Cerro Toledo sediments that apparently accumulated in a broad east-southeast-trending drainage incised into the top of the Otowi Member. On the eastern side of the plateau, the Otowi Member is 0 to 100 ft thick. Thinning of the deposits eastward reflects both the general thinning of the Otowi Member away from its caldera source and thinning of the ash-flow tuffs over the Cerros del Rio highland on the east side of the plateau. Structure contours indicate that Otowi ash-flow tuffs filled a broad south-draining paleovalley west of the Cerros del Rio basaltic highland.

Figure 2-5 shows structure contours (red dashed lines) at the base of the Otowi Member of the Bandelier Tuff and color shading in purple that represents relative overall thickness of the unit. The Otowi Member thickens from the central portion of the Laboratory toward the west, with the exception of a paleocanyon that is aligned with and filled by the thick Cerro Toledo deposits shown in Figure 2-5. To the east, south of PM-1 where Otowi deposits ramp up onto the Cerros del Rio basaltic volcanic centers with little or no Puye sediment cover, the Otowi deposits are thinner than to the northeast where they are underlain mostly by eastward-sloping Puye fans. In the south-central portion of the Laboratory the Otowi deposits fill a broad south-trending valley formed by low terrain between Puye fans sloping down from the west and Cerros del Rio highlands to the east, such as the TA-33 volcano.

The Guaje Pumice Bed occurs at the base of the Otowi Member and is an extensive marker horizon in outcrop and wells. The Guaje Pumice Bed contains layers of sorted pumice fragments

whose mean size varies between 2 and 4 cm. It has an average thickness of ~15 ft over much of the plateau, but thickens considerably to the northwest (Figure 2-6). Geophysical logs show that the Guaje Pumice Bed has a higher porosity than overlying Otowi ash-flow tuffs and underlying Puye Formation. The Guaje Pumice Bed appears consistently as a zone of higher porosity and elevated moisture content in CMR geophysical logs. Because of this property the Guaje Pumice Bed can provide a relatively thin (a few feet to a few tens of feet) but laterally continuous horizon capable of local saturation.

Figure 2-6 uses color shading to represent the thickness of the Guaje Pumice Bed. Because the Guaje Pumice Bed formed as a pumice fall rather than an ash flow, the tendency to thin away from the source (the Valles caldera) is much less pronounced except for the area underlying the northwestern corner of the Laboratory. The distribution of pumice fall deposits is more strongly influenced by prevailing wind direction at the time of eruption, compared with the largely internal energy sources that distribute ash flows. A general lack of incision and weathering at the top of the Guaje Pumice Bed indicates that little time elapsed before it was buried by magmatically related ash flows of the Otowi Member. Locally, however, the Guaje Pumice is unusually thin compared to surrounding areas and may have been partially eroded before or during the passage of the earliest Otowi ash flows. In the eastern portion of the Laboratory the Guaje Pumice Bed is seldom more than a few feet thick and is locally absent.

2.2.9.2 Tephra and Volcaniclastic Sediments of the Cerro Toledo Interval

The Cerro Toledo interval crops out in Los Alamos Canyon and in canyons to the north, and it occurs in many of the wells on the plateau. It unconformably overlies the deeply eroded Otowi Member and its thickness is highly variable (3 to 390 ft). Figure 2-4 shows structure contours at the base of the Cerro Toledo interval and a colored representation of relative overall thickness of the unit. Structure contours for the base of the Cerro Toledo indicate that this unit fills a broad southeast-draining valley fed by one or more canyons exiting the Sierra de los Valles. The thickest Cerro Toledo deposits coincide with the axis of this paleovalley.

The predominant rock type in the Cerro Toledo interval is rhyolitic tuffaceous sandstone and tephra. These deposits contain abundant crystal-poor ash and pumice, and clasts of vitric to devitrified rhyolite lava and minor obsidian. They represent the reworked equivalents of Cerro Toledo Rhyolite tephra erupted from the Cerro Toledo and Rabbit Mountain dome complexes located northeast and southeast of the Valles caldera, respectively. Primary pumice-and ash-falls are interbedded with these sedimentary deposits in most locations.

Clast-supported gravel, cobble, and boulder deposits of porphyritic Tschicoma dacite derived from the Tschicoma Formation are also interbedded with the tuffaceous rocks. In some deposits, the dacitic detritus is volumetrically more important than the tuffaceous detritus. These coarse dacitic deposits commonly define the axial portions of channels incised into the underlying Otowi Member.

In the western part of the plateau, the Cerro Toledo interval contains a large component of crystal-rich tuffaceous detritus. These tuffaceous sediments represent reworked Otowi tuff that accumulated in drainages incised into the Otowi Member prior to emplacement of the Tshirege

Member. These reworked Otowi deposits are interbedded with other volcaniclastic deposits derived from Cerro Toledo and Tschicoma sources.

Data from boreholes R-19, CdV-R-15-3, CdV-16-1(i), R-18, and R-26 revised the conceptual model for the Cerro Toledo interval, which was a general thinning from Cerro Toledo age volcanic sources in the caldera to the northwest of the Laboratory to distal deposits toward the east-southeast (Broxton and Vaniman, 2005). These boreholes, however, showed that the thickening is not uniform and the Cerro Toledo sediments fill a deep and broad east-southeast draining paleocanyon in the middle western portion of the Laboratory. This paleocanyon is incised into the top of the Otowi ash flows; the overlying base of the Tshirege Member of the Bandelier Tuff and the underlying base of the Otowi Member (Figure 2-5) show no such canyon development. The structure contours that show the base of the Cerro Toledo interval in Figure 2-4 show the topology of the canyon eroded into the top of the Otowi ash flows. The exact width and the orientation of this canyon, whether it is one canyon or several, and where this canyon connected to paleodrainages toward the Rio Grande to the east are relatively unconstrained points that allow a certain amount of latitude in the way that Figure 2-4 is constructed.

2.2.9.3 Tshirege Member, Bandelier Tuff

The Tshirege Member is the upper member of the Bandelier Tuff and is the most widely exposed bedrock unit of the Pajarito Plateau. It is a multiple-flow, ash-and-pumice sheet that forms the prominent cliffs throughout the plateau. It also underlies canyon floors in all but the middle and lower reaches of Los Alamos Canyon and in canyons to the north. The Tshirege Member is generally over 200 ft thick in the north-central part of LANL and over 600 ft thick near the southern edge of LANL.

The Tshirege Member differs from the Otowi Member most notably in its generally greater degree of welding compaction. Time breaks between the successive emplacements of ash-flow units caused the tuff to cool as several distinct cooling units. For this reason the Tshirege Member is a compound cooling unit, consisting of at least four cooling subunits that display variable physical properties vertically and horizontally. These variations in physical properties reflect zonal patterns of varying degrees of compaction, welding, and glass crystallization. The welding and crystallization zones in the Tshirege Member produce vertical variations in properties such as density, porosity, hardness, composition, color, and surface weathering patterns. The degree of welding in each of the cooling units generally decreases from west to east, reflecting higher emplacement temperatures and thicker deposits closer to the Valles caldera.

The Tsankawi Pumice Bed forms the base of the Tshirege Member. Where exposed, it is commonly 2 to 3 feet in thickness. This pumice-fall deposit contains sorted pumice lapilli (diameters reaching about 2.5 in) in a crystal-rich matrix. Several thin ash beds are interbedded with the pumice-fall deposits.

Because the thick Tshirege ash flow tuffs make up a significant portion of the upper vadose zone, brief descriptions are provided below for the major subunits of the member, from bottom to top:

- **Qbt 1g** is the lowermost subunit above the Tsankawi Pumice Bed. It consists of porous, nonwelded, and poorly sorted ash-flow tuffs. The "g" in this designation stands for "glass" because none of the glass in ash shards and pumices shows crystallization by devitrification or vapor phase alteration. The tuffs of Qbt 1g are nonwelded and have an open, porous structure.
- **Qbt 1v** forms alternating cliff-like and sloping outcrops composed of porous, nonwelded, but crystalline tuffs. The "v" stands for vapor-phase crystallization that together with crystallization of glass in shards and pumices (devitrification) transformed the rock matrix into microcrystalline aggregates of silica polymorphs and sanidine. The tuffs of Qbt 1v are generally nonwelded to slightly welded, and have an open, porous structure.
- **Qbt 2** forms a distinctive, medium brown, vertical cliff that stands out in marked contrast to the slope-forming, lighter colored tuffs above and below. A series of laminated and cross-bedded deposits commonly mark its base in the eastern part of the Laboratory. In the central and western part of the Laboratory, the boundary between Qbt 2 and Qbt 1v is gradational and the distinction between the two units is somewhat arbitrary. Qbt 2 is typically the most strongly welded tuff in the Tshirege Member. Vapor-phase crystallization of flattened shards and pumices is extensive in this subunit.
- **Qbt 3** is a nonwelded to partly welded, vapor-phase altered tuff that forms the cap rock of mesas in the central part of the Pajarito Plateau. Qbt 3 becomes moderately to densely welded in the western part of the plateau.
- **Qbt 4** is a complex unit consisting of nonwelded to densely welded ash-flow tuffs and thin intercalated surge deposits. Devitrification and vapor-phase alteration are typical in this unit, but thin zones of vitric ash-flow tuff occur locally. The occurrence of Qbt 4 is limited to the western part of the Pajarito Plateau.

2.2.10 Alluvium and Colluvium

Holocene and late Pleistocene canyon-floor alluvium consists of stratified, lenticular deposits of unconsolidated fluvial sands, gravels, and cobbles (Reneau et al., 1996). Smaller canyons whose headwaters are located on the plateau contain detritus exclusively of Bandelier Tuff. Larger canyon systems that head in the Sierra de los Valles contain Bandelier detritus mixed with dacite detritus derived from the Tschicoma Formation. Active and inactive channels and floodplains form complex, cross-cutting deposits. These fluvial sediments interfinger laterally with colluvium derived from canyon walls. In Pueblo Canyon alluvium is about 11 ft thick on the west side of the plateau and about 18 ft thick near the confluence with Los Alamos Canyon. Mortandad Canyon has 1 to 2 ft of alluvium near its headwaters and more than 100 ft of alluvium (plus colluvium) near the eastern LANL boundary.

Alluvium of probable early Pleistocene age overlies Bandelier Tuff on mesas throughout the plateau (Reneau and McDonald, 1996). The alluvial deposits form fairly continuous deposits on the western side of the plateau, but only remnants of these deposits are preserved further east. These alluvial deposits are primarily made up of coarse dacitic detritus from the Sierra de los Valles, but some locations also contain Valles Rhyolite (Cerro del Medio and El Cajete) fall deposits or their reworked equivalents. These deposits record the locations post-Tshirege alluvial fans and streams that predate incision of canyons on the plateau (Reneau and McDonald, 1996).

Colluvium consists of slope or cliff detritus shed gravitationally into canyons. In most instances only large blocks of colluvium can be distinguished from locally derived alluvium, where the colluvial blocks are identified with material in adjacent cliffs. Colluvial blocks are commonly overlain by alluvium, as in the wider reaches along Mortandad Canyon where blocks of upper devitrifed units of the Tshirege Member, often several feet in diameter, are found beneath alluvial sands and gravels in drillhole MCOBT-8.5.

2.3 Geologic Conceptual Model Cross-Sections

The geologic conceptual model is based on the accumulated geologic, geophysical, and hydrogeologic data described in Section 2.1. Regional and local data sources are used to constrain possible visualizations of the thickness and extent of major hydrogeologic units beneath the Laboratory. Of all data sources, the principal sources for building the subsurface components of the geologic conceptual model are obtained through the R-hole drilling program conducted under the Hydrogeologic Workplan. These data are supplemented by drilling data collected from boreholes that were drilled for other purposes. Because samples and geophysical logs from earlier boreholes are largely unavailable, and earlier wells were not drilled with the goal of obtaining a sitewide hydrogeologic model, the R-series wells provide the best available dataset for subsurface geology at the Laboratory. The various types of stratigraphic data from R-series wells and from other boreholes used to support the geologic conceptual model are summarized in Appendix 2-A.

2.3.1 Geology at the Water Table

The distribution of bedrock units at the top of regional saturation is shown in Figure 2-10. Regional groundwater enters the Pajarito Plateau by underflow through the rocks that underlie the Sierra de los Valles (Griggs, 1964; Purtymun, 1984). This underflow is supplemented by recharge from drainages that cross the plateau (Kwicklis et al., 2005). Hydrogeologic conditions beneath the Sierra de los Valles west of the Pajarito fault zone are largely unknown because there are no deep wells in this area. Groundwater probably flows through Tschicoma lavas and underlying geologic units at depth, based on stratigraphic cross-sections (see Section 2.3.2). The geologic units beneath the Tschicoma Formation are poorly constrained but probably consist of Keres Group volcanic rocks, Santa Fe Group sediments, Eocene sedimentary rocks, Paleozoic and Mesozoic sedimentary rocks, and Precambrian crystalline rocks (Smith et al., 1970; Goff and Gardner, 2004; Smith, 2004). In the western part of the plateau, in the vicinity of Pueblo and Water Canyons, the water table is straddled by two lobes of down-faulted Tschicoma lavas that extend up to 3 km (2 mi) east of the Pajarito fault zone. Based on the physical characteristics of the rocks, groundwater flow through dacite most likely occurs as fracture flow in the lava interiors and as porous flow in interflow zones and interbedded clastic deposits.

In the central part of the plateau, the regional water table occurs within basin-fill deposits that become progressively older to the east. These basin-fill deposits consist of the Puye Formation, pumice-rich volcaniclastic rocks, older fanglomerates, and the Tesuque Formation (Figure 2-10). The most productive municipal supply wells on the plateau occur in this area where long well

screens (500 m [1600 ft]) span the Puye Formation, pumiceous deposits, Totavi deposits, older fanglomerates, and Tesuque sedimentary rocks and basalts.

Basalt straddles the water table in two areas. The most extensive is located in the south-central part of the plateau where as much as 195 ft of saturated Pliocene Cerros del Rio basalt occurs at the top of the regional zone of saturation in well DT-10 and 290 ft occurs in well R-22 (Figure 2-10). A smaller region of older Miocene basalts straddles the water table in a north-trending zone extending between wells R-12 to R-5. The southern extent of this zone is poorly constrained.

The Tesuque Formation is the primary rock unit making up the regional aquifer in the eastern part of the plateau and in the Buckman well field east of the Rio Grande (Figure 2-10). Miocene basalts are interbedded with the Tesuque Formation beneath parts of the plateau, but are absent in wells drilled to depths of 300 to 575 m (1000 to 1900 ft) in the Buckman well field (Shomaker, 1974). Most of the production from municipal supply wells in Guaje Canyon and in lower Los Alamos Canyon comes from the Tesuque Formation.

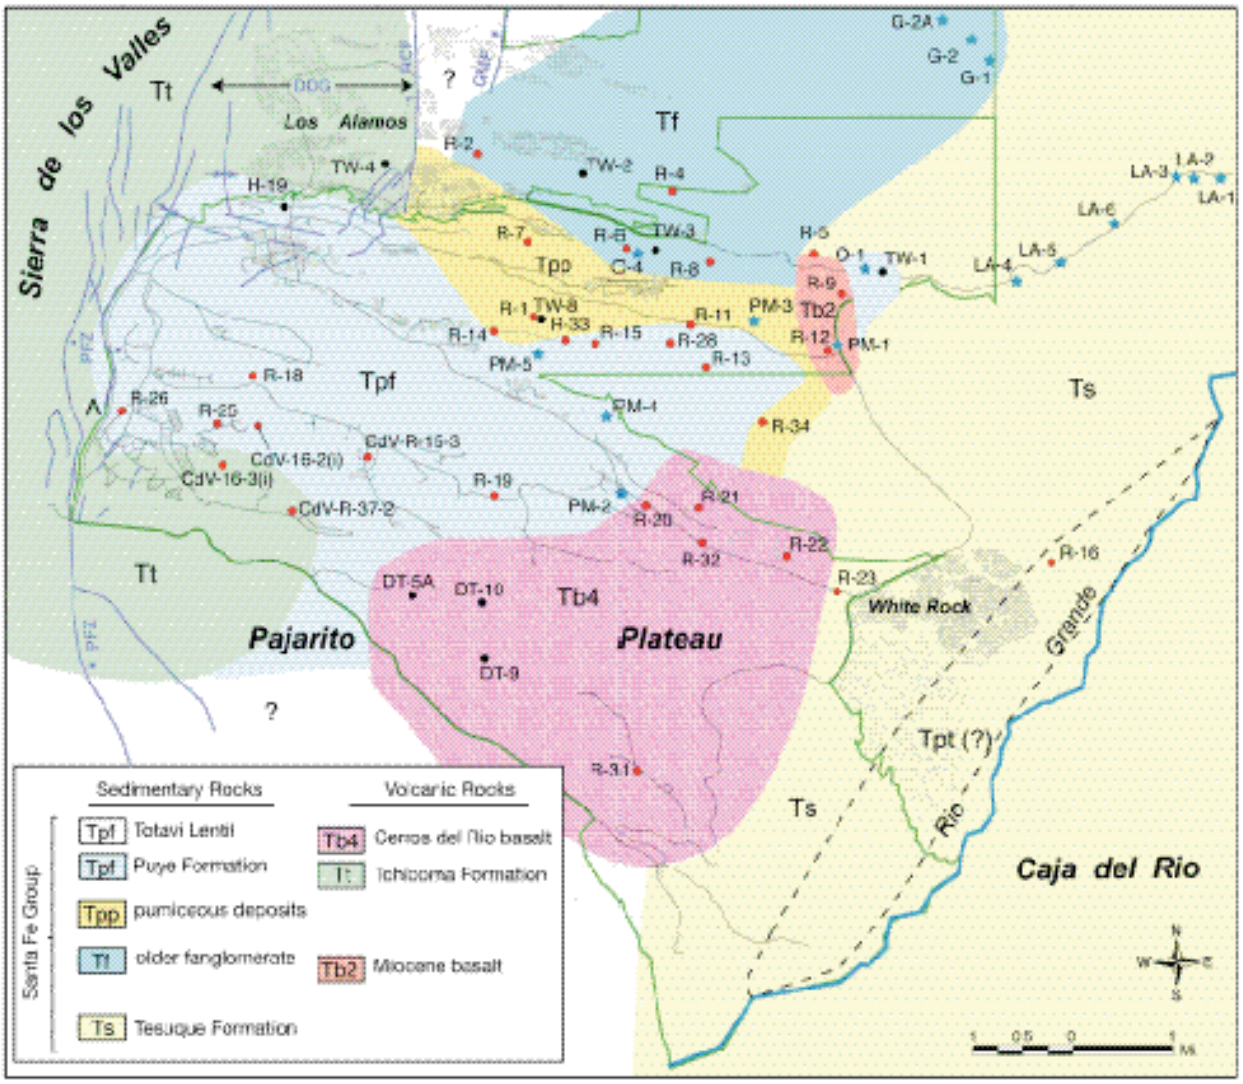

Figure 2-10. Map showing distribution of geologic units at the top of the regional saturated zone beneath the Pajarito Plateau. The wells that provided geologic control for this map are indicated by dots using the same color schemes as Figure 2-2. The LANL boundary is shown by the green outline, and the Pajarito fault zone is shown in blue. The map portrays the dominant rock unit in the upper 50 ft of the regional saturated zone.

2.3.2 Representative Cross-Sections

The full three-dimensional implementation of the geologic model is discussed in Section 4.1. The 3D model is tested against conceptual cross-sections that incorporate time-stratigraphic constraints, structural considerations, and correlations and limitations that take into account source regions and settings beyond the boundaries of the 3D model. The development of a manageable 3D model is time-intensive and requires treatment of geologic units on a large scale, where some details must necessarily be incorporated into larger units or ignored. Conceptual cross-sections help to test ideas concerning site geology, present details that may not be manageable in the 3D model, and provide a means of rapid testing of new borehole data against existing concepts.

Figure 2-11 shows alignments for eight conceptual geologic cross-sections that cover the Laboratory area. Included are four conceptual cross-sections for principal drainages:

- Los Alamos Canyon (Figure 2-12),
- Mortandad Canyon (Figure 2-13),
- Pajarito Canyon (Figure 2-14), and
- Water Canyon (Figure 2-15).

In addition, four cross-sections of approximately southwest-northeast alignment cross the grain of drainage at the Laboratory from western to eastern portions of the site (Figures 2-16, 2-17, 2-18, 2-19). Each geologic section is presented here at a vertical exaggeration of 10:1 in order to permit appropriate labeling and allow a level of detail that would not be possible at true vertical scale. Each geologic section is described separately below.

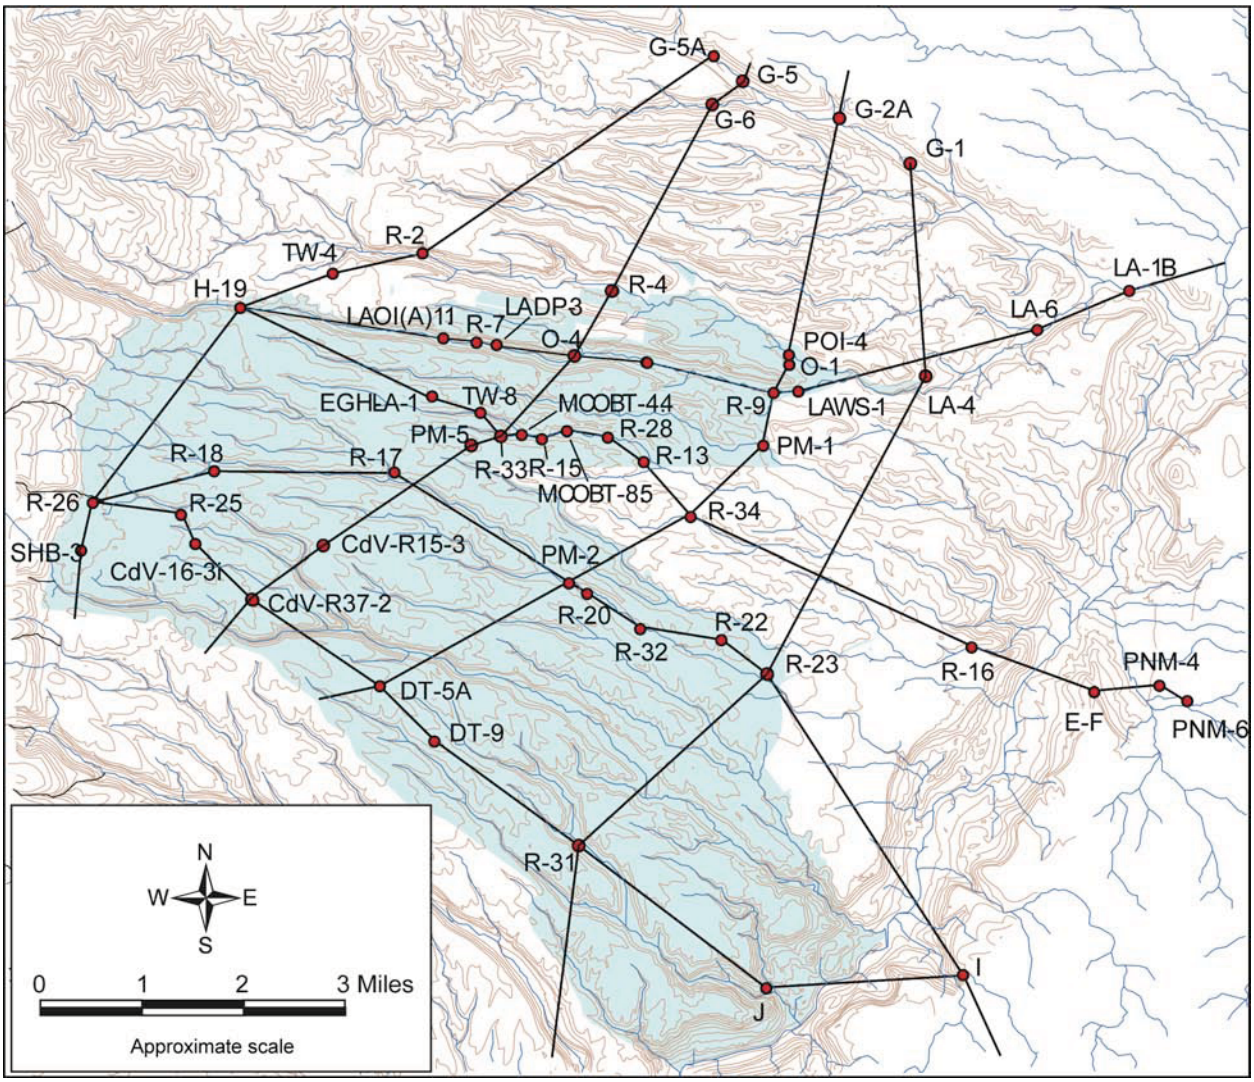

Figure 2-11. Lines of cross-section for Figures 2-12 through 2-19.

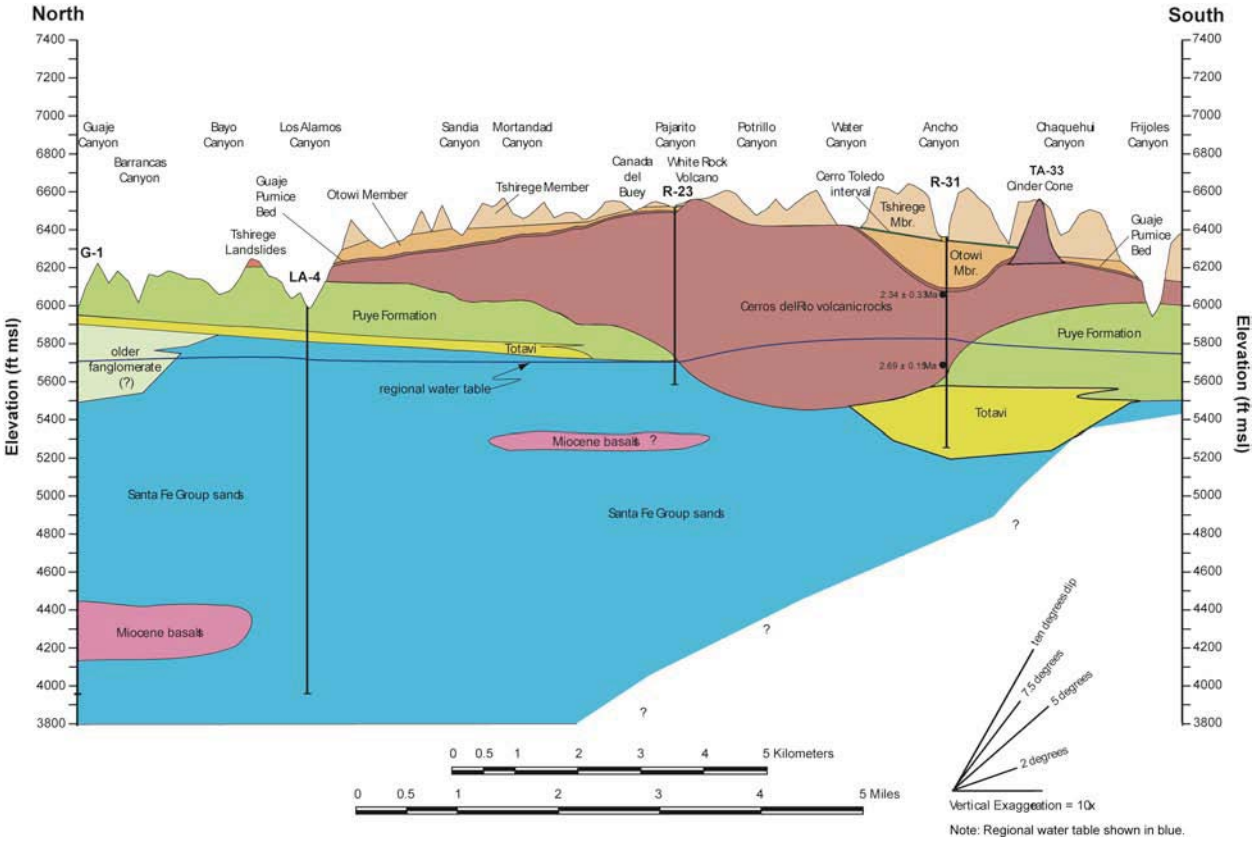

Figure 2-19. Conceptual north-south cross-section through the eastern portion of the Laboratory.

2.3.2.1 Los Alamos Canyon Cross-Section

Figure 2-12 shows a cross-section based on boreholes along the length of Los Alamos Canyon, from H-19 to the Rio Grande. At the western margin of this section, thick Tschicoma lava flows are shown extending almost to the Rendija fault zone or slightly beyond. The lack of dacitic lavas in R-7 suggests that the lavas do not extend this far to the east; however, lithologic homogeneity of dacitic lithologies in thick Puye fanglomerate sequences at R-7 may indicate that the dominant lava sources are not far away. From the opposite direction, Cerros del Rio lavas extend from exposures in lower Los Alamos Canyon to O-4 but not to R-7. The "lava gap" at R-7 provides a section of more homogeneous lithology (Bandelier, Puye, and pumice-rich volcaniclastic rocks) from canyon bottom to regional water table without interference from low-porosity dacitic or basaltic lava flow.

Pumice-rich volcaniclastic rocks at R-7 occur in a series of primary or reworked pumice beds intercalated with fanglomerates. In this cross-section these are referred to as "younger pumiceous deposits" to distinguish them from heavily clay-altered and possibly older pumice deposits observed at greater depth in O-4, R-8, and in R-9. In reality these may be unaltered and altered variants of a single unit and the distinction shown here may be abandoned if future studies provide a link between these deposits. The lenses and thin layers labeled as "river gravels" refer to well-rounded gravels that contain at least 10% Precambrian lithologies (quartzite, with and without granite and schists, etc.). As noted in Section 2.2.4, relationships between these gravels and the Totavi are uncertain.

Dips on hydrostratigraphic units in this cross section vary with age; the youngest units dip to the east and older units dip to the west. This variation in dip reflects in part the progressive drop in structural elevation along the Pajarito fault zone, just west of H-19. Younger contributions of Tschicoma lavas, steep fanglomerate slopes shed from these fans, and proximally thick Bandelier ash flows provide the east-dipping masses at higher stratigraphic levels.

2.3.2.2 Mortandad Canyon Cross-Section

Figure 2-13 shows a cross-section beginning at borehole H-19, dropping into Mortandad Canyon at TW-8 and extending along Mortandad Canyon, then to R-16 and across the Rio Grande to well PNM6 in the Buckman well field. This cross section begins in the west where Tschicoma dacitic lavas were found in drillhole H-19, but here the uppermost lavas are extended to borehole EGH-LA-1. The implied relationship between dacitic lavas in these two drillholes is speculative because there are no samples from H-19 to test similarity. If there is continuity of dacitic lavas between H-19 and EGH-LA-1 to the west as shown, then there is likely little or no "lava gap" between Tschicoma dacites and Cerros del Rio basalts as seen in the vicinity of R-7 in Figure 2-12.

The top of the pumiceous deposits, beneath Puye fanglomerates, is well defined in boreholes from TW-8 to R-13. The data from EGH-LA-1 and R-34 are largely inferred due to poor sample returns in these drillholes. There is also a lack of information to indicate whether or not there is a series of clay-altered and possibly older pumiceous deposits, as shown in Figure 2-12, on top of the Miocene basalts shown here. As in the previous cross-section for Los Alamos Canyon, dips on most units vary from easterly in upper horizons to westerly in lower horizons. The evidence for westerly dips in Santa Fe Group sands for this section is based largely on extrapolation from

the FMI dips recorded in drillhole R-16 (see Table 1-A-1). The pumice-rich volcaniclastic deposits dip 5-7° to the southwest at R-1 and R-33 and 6 ° to the southeast at R-28.

The south-trending paleocanyon at the base of the Bandelier Tuff is more evident in this section than in the more northerly section along Los Alamos Canyon (Figure 2-12). In Figure 2-13 the axis of the paleocanyon is clearly transected in the vicinity of drillholes R-33 to MCOBT-8.5. Evidence for a comparable canyon, offset to the east, may be seen in the depth to pumiceous deposits at R-13, but the paucity of deep cuttings from R-34 make this interpretation somewhat speculative. Evidence for the cinder mass within the Cerros del Rio at R-34 however is very good, and it is likely that a buried basaltic vent source is close to the R-34 drill site, although the distance and direction to the vent are not constrained.

2.3.2.3 Pajarito Canyon Cross-Section

Figure 2-14 shows a cross-section beginning at borehole R-26, extending to the location of well R-18 and planned well R-17, then along Pajarito Canyon to well R-23 and across the Rio Grande to a measured section on the eastern canyon wall (Dethier, 1997). In this cross section the deep erosion into the Otowi ash flows and filling of this eroded canyon by Cerro Toledo deposits is evident (compare with Figures 2-4 and 2-5). As in the Mortandad Canyon cross section, the broad south-trending valley filled by Bandelier Tuff is visible west of PM-2, although placement of the valley axis will depend on observations yet to be obtained from future drillhole R-17.

The deepest point filled by Cerros del Rio lavas in this section is at R-22. This point is the principal evidence for the south-trending paleocanyon seen in Figure 2-8, although the exact trend and the head of the canyon are poorly constrained by current borehole data. The west-dipping Miocene basalts are suggested by dips seen in other drillholes to the north, in outcrop along White Rock Canyon (Dethier, 1997), and by suggested correlations between Miocene basaltic lavas in PM-2 and R-22 and between PM-2 and basalt outcrops in White Rock Canyon. At R-20, FMI logs show that the pumice-rich volcaniclastic deposits dip about 5° to the southwest.

2.3.2.4 Water Canyon Cross-Section

The cross-section shown in Figure 2-15 runs approximately parallel to the southern boundary of the Laboratory, from borehole R-26 to two measured sections on the western and eastern walls of White Rock Canyon (Dethier, 1997). Here the axis of the paleocanyon at the base of the Bandelier Tuff is less evident because the eastern wall of that paleocanyon is essentially flat, from borehole DT-9 to White Rock Canyon. An older and more prominent paleocanyon is shown in the vicinity of borehole R-31, filled by accumulation of largely Precambrian sands and gravels marking a previous channel of the ancestral Rio Grande. The depth of this paleochannel is poorly known because borehole R-31 was unable to penetrate completely through the gravel deposit.

Boreholes CdV-16-3(i) and CdV-R-37-2 were both completed within thick sequences of Tschicoma Formation dacitic lavas. These lavas do not occur in borehole R-25; moreover, lavas encountered in boreholes DT-5A and DT-9 are poorly characterized but are believed to be flows within the Cerros del Rio volcanic field that are likely younger than these thick dacitic lavas, although no samples of these lavas are available for dating. Completion of planned drillhole

R-27 within Water Canyon north of DT-5A will address this question by providing samples of these lavas. Specifically, the well will provide additional information about the composition of lavas in the vicinity of TA-49 and their possible relationship with the lavas encountered in CdV-16-3(i) and CdV-R-37-2. In this cross-section the dacitic lavas in CdV-16-3i and CdV-R-37-2 are shown as being limited in lateral extent. The flow base for these lavas is speculated to be at the top of the older fanglomerates, but actual stratigraphic relations are unknown at this time.

2.3.2.5 Western Boundary Cross-Section

Figure 2-16 shows a cross-section from south of borehole SHB-3 extending up along the western boundary of the Laboratory, northeast to borehole G-5A in Guaje Canyon. This section shows in cross-section the depth and width of the paleocanyon cut into the Otowi Member and filled by deposits of the Cerro Toledo interval in the vicinity of borehole R-26. To the north the Otowi Member has been eroded away and the sediments of the Cerro Toledo interval are deposited on fanglomerates of the Puye Formation. Fanglomerates of the Puye Formation are considerably thicker beneath the Laboratory than to the north. The pumice-rich volcaniclastic and older fanglomerate are believed to occur beneath the western part of LANL but their presence is speculative because boreholes do not fully penetrate the thick Puye Formation in that area. The correlation of dacitic lavas in TW-4 and H-19 is based on lithologic descriptions of phenocryst minerals, but the lack of available cuttings from these boreholes means that this correlation cannot be tested.

2.3.2.6 West-Central Cross-Section

Figure 2-17 shows a cross-section from south of borehole CdV-R-37-2 and extending northeast across the Laboratory to borehole G-5 in Guaje Canyon. In this section the chemical composition of the lavas (wt% SiO_2) and available radiometric ages are shown to indicate how the lavas can be used as a guide in stratigraphic interpretation. In general, the ages of lavas assigned to the Cerros del Rio volcanic field or to the older Miocene sequences correlate with stratigraphic depth. The Tschicoma intermediate-composition lavas at the margins of the Laboratory, as in borehole CdV-R-37-2, have not been fully penetrated by any boreholes and the nature of their basal contacts is not known.

As in Figure 2-15, the pumiceous deposits and the underlying river gravels (Totavi) are shown with a southern component of dip, consistent with FMI dip information described earlier. The river gravels can be extended as a continuous unit between boreholes R-33 and PM-5. However, another interpretation would be as unconnected river channels at different elevations, as seen in the east-central cross-section to the east (Figure 2-18).

The cross-section suggests that there is considerable incision into the top pf the Santa Fe Group sands prior to deposition of the older fanglomerate in the vicinity of O-4. This interpretation is supported by the presence of younger Miocene basalts at O-4 that occur at the same structural levels as older Miocene basalts beneath Guaje Canyon. The orientation of possible paleovalleys incised into Santa Fe Group sands cannot be determined because most boreholes in the central and western part of the plateau are not deep enough to penetrate the base of the older fanglomerates. Relations described by Griggs (1964) for wells in the Guaje Canyon areas suggest that some uppermost Santa Fe Group sands interfinger with the older fanglomerate.

2.3.2.7 East-Central Cross-Section

Figure 2-18 shows a cross-section from southwest of borehole DT-5A extending northeast across the Laboratory to drillhole G-2A in Guaje Canyon. This section crosses a high point in the Cerros del Rio volcanic field at borehole R-34. As in the western-boundary and west-central cross-sections (Figures 2-16 and 2-17) the stratigraphy beneath the Bandelier Tuff at the southern Laboratory boundary is speculative. If the lavas penetrated by borehole DT-5A are attributed to the Cerros del Rio (see Figure 2-8) rather than the Tschicoma Formation, the distinction from Cerros del Rio volcanic rocks shown as a contact here may unnecessary. The lack of samples for analysis from borehole DT-5A allows either interpretation, but this problem should be resolved when borehole R-27 is completed in Water Canyon north of DT-5A.

Petrographic and radiometric data from lavas outcropping in Bayo Canyon and comparable data from lavas in borehole R-9 suggest an offset of several hundred feet down to the south, interpreted in this cross section as a normal fault between Bayo and Pueblo canyons, covered by and not offsetting the Bandelier Tuff. Other explanations are possible but fault offset is supported by observed offset of exposures in Bayo Canyon. The number and distribution of faults beneath the Laboratory remains largely unknown, but continuity in many younger units, particularly the Bandelier Tuff and Cerros del Rio volcanic rocks, limits the amount of significant fault offset in the central and eastern Laboratory area to units older than about 3 Ma. As in Figure 2-17, the cross section shows a paleovally incised into the top of Santa Fe Group sands filled by older fanglomerate. These relationships are based on descriptions of the pre-Puye rock units described in the lithologic logs for PM-1, PM-2, and DT-5A, and they cannot be verified because drill cuttings for these wells are not available.

2.3.2.8 Eastern Cross-Section

Figure 2-19 shows a cross-section from south of borehole R-31 extending northeast and then north across the eastern portion of the Laboratory to drillhole G-1 in Guaje Canyon. This figure illustrates the thinning and local absence of the Otowi Member of the Bandelier Tuff over highlands of Cerros del Rio volcanic rocks. The very thick sequence of Cerros del Rio volcanic rocks between boreholes R-23 and R-31 has a total depth that is poorly constrained but likely to have filled a paleocanyon (see Figure 2-8). Continuity of Totavi river gravels from north to south is shown as disrupted in the vicinity of this paleocanyon, for such gravels are missing in several boreholes near this feature. At greater depth the stratigraphic sequence is dominated by Santa Fe Group sands, based on evidence from boreholes in lower Los Alamos Canyon (e.g., LA-4), boreholes to the east (R-16), and exposures mapped in White Rock Canyon (Dethier, 1997).

2.4 Hydrologic Properties

The geologic units of the Pajarito Plateau are organized into more generalized hydrogeologic units that form the framework for flow and transport numerical models (Section 4). Hydrogeologic units are subdivided based on lithologic characteristics believed to result in different hydrologic properties. A comparison of geologic and hydrologic frameworks for the plateau region is provided in Figure 2-3.

2.4.1 Vadose Zone Hydrologic Properties

The vadose zone, the region between the ground surface and the regional aquifer, consists of variably saturated rocks, and locally saturated zones. The hydrologic properties controlling the flow of water from the surface to the regional aquifer are the saturated hydraulic conductivity (ksat) and the unsaturated hydraulic properties. As explained in basic hydrology texts and in references related to the vadose zone beneath the Pajarito Plateau such as Rogers and Gallaher (1995), when rocks are not completely saturated, the moisture retention curve defines the relationship between the volumetric water content of a soil or rock and its capillary pressure (sometimes referred to as the matric suction or matric potential). As the pores fill with water, capillary forces result in the small-diameter pores filling first, and at progressively larger water contents, the larger pores fill. The resistance to flow is much lower for the large-diameter pores, so that the unsaturated hydraulic conductivity increases as a strong function of the water content, reaching a maximum when the medium is saturated. Under unsaturated conditions, the local water content and matric potential are controlled by the percolation flux; the local values of these variables modulate themselves in response to changes in the local percolation rate, in order that fluid may pass through the rock under gravity-driven or capillary-flow conditions. For unsaturated conditions flux and water content are related and flow is in response to a gradient that is composed of capillary and gravitational terms.

Although most contaminants of concern associated with past LANL operations travel in the liquid phase, gas-phase transport is an important mechanism for radon and also for various volatile organic chemicals present in the subsurface. Furthermore, vadose zone observations used to estimate permeability at larger scales tend to be pneumatic, that is, based on the response of gas-phase pressures to changes in the air pressure exerted at the surface. When treating vapor transport, the permeability to the gas phase is the relevant property. Although in principle the permeability of the medium should be independent of the fluid (air or water), the role of fractures and issues of scale dependence come into play. Given that open fractures are most likely to be air-filled under ambient conditions, fractures dominate the behavior for gas-phase contaminant transport and the interpretation of pneumatic data.

To quantify the scale dependence of permeability of the Bandelier Tuff and to demonstrate the role of fractures, permeability estimates across all scales from laboratory samples to the scale of a mesa have been compiled. For the Laboratory scale, the geometric mean values of saturated hydraulic conductivity reported by Rogers and Gallaher (1995) are used, and water properties at standard conditions are used to convert conductivities to permeabilities. Parameter estimates for larger scales include gas-phase permeability estimates from Neeper (2002) for the tuff, and hydraulic conductivity measurements for the basalts from Stauffer and Stone (2005). In that study, Neeper (2002) presents field-scale results of pneumatic testing using straddle packers, and larger scale estimates based on the interpretation of the pressure responses to barometric cycles. The packer tests are termed “intermediate scale,” and the estimates based on response to barometric cycles are called the “large scale.”

Figure 2-20 compares the permeability estimates for the three scales. The laboratory scale values represent matrix permeability and discount the role of fractures, as unfractured samples were typically tested. Permeability values are at least one order of magnitude smaller than the

Intermediate-scale estimates. The large-scale values are similar to the intermediate scale, except in certain highly fractured regions, where even higher estimates of permeability are made. The most striking difference with scale is for the Cerros del Rio basalt, where core samples represent competent, low-permeability rock, whereas the field scale is dominated by large, open fractures or cavities that transmit air with virtually no resistance. Field observations in the basalts indicate that pressure changes at the surface are transmitted rapidly to depth (Neeper, 2002).

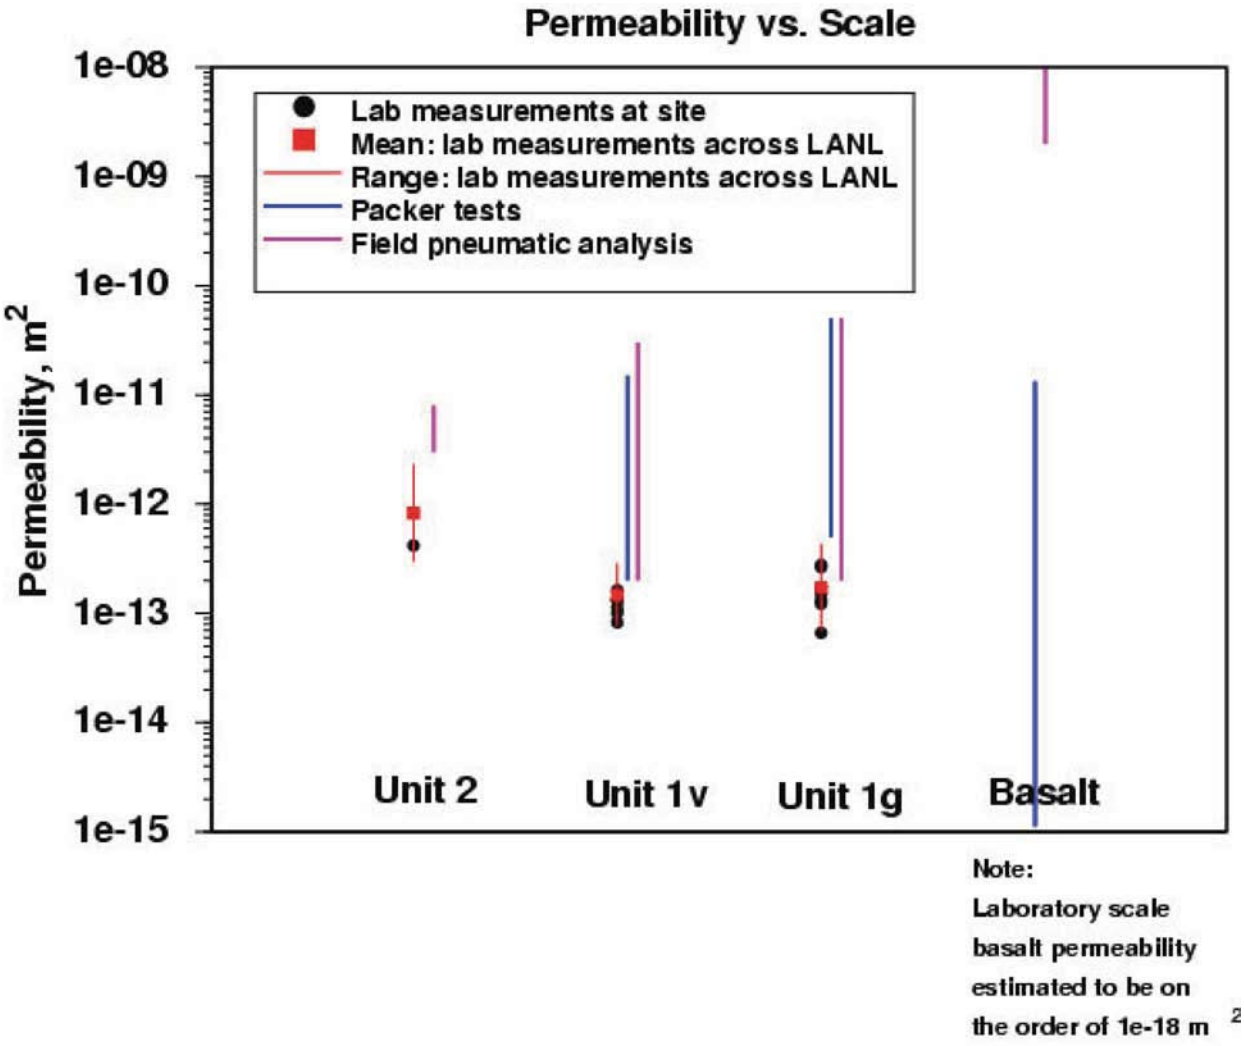

Figure 2-20. Permeability as a function of measurement scale for Bandelier Tuff (units 1g, 1v, and 2) and basalts.

These results illustrate the role of measurement scale and rock type on estimating the effective permeability of the rocks in the vadose zone. Clearly, fractures, faults, or other large-scale features exert control on the properties of the rock as scale increases. In this comparison, we have mixed the results of water and air flow observations to examine the role of scale. While it is apparent that the role of fractures in transmitting air through the vadose zone must be considered, the question of water flow and the role of fractures must also be considered. Robinson et al. (2005) provide field evidence and numerical model results that suggest that the Bandelier Tuff transmits water through the porous and permeable matrix even for cases in which water is injected at very high percolation rates. Furthermore, the hydrologic properties measured in samples collected from boreholes suffice to describe the percolation of water through the Bandelier Tuff under unsaturated conditions. That study concluded that as long as the percolation rate is lower than the local saturated hydraulic conductivity, water initially present in fractures is imbibed into the rock matrix. Therefore, rock properties of the matrix are most important, except perhaps near the surface where high-fracture-density zones may coincide with regions of high local infiltration rate. Matrix flow is an important simplification that makes vadose-zone characterization in individual canyons a more tractable problem.

In contrast to the Bandelier Tuff, the basaltic rocks clearly exhibit rapid flow through fractures and other fast pathways, and the permeability of the rock matrix is essentially irrelevant to the rates of water percolation (Stauffer and Stone, 2005). The difference is the orders of magnitude lower matrix permeabilities of these rocks, compared to the Bandelier Tuff.

2.4.2 Regional Aquifer Hydrologic Properties

Aquifer properties that are relevant to issues of groundwater quality and quantity are hydraulic conductivity, specific yield (unconfined aquifer) or storativity (confined aquifer), and effective porosity. This subsection summarizes all available information, both recent data collected in R-wells and older estimates from water supply wells. No new information on storage properties of the rocks has been collected in R-wells; this discussion, therefore, will rely entirely on older data.

There are inherent uncertainties associated with any particular estimate of aquifer properties, and there are two particularly important issues to consider when assessing these estimates. First, at the field-scale, these are quantities that are virtually impossible to measure directly. They can only be measured indirectly, via measuring the response of the aquifer to stress, then applying a theoretical model to that response. In a particularly complex aquifer such as the one beneath the Pajarito Plateau, the models used to interpret aquifer tests are necessarily much simpler than the actual aquifer and this will affect the accuracy of the test interpretation. Second, in a complex aquifer, hydraulic conductivity will vary substantially depending on the scale over which it is measured. Tests conducted in wells with long screens (such as water supply wells) and/or tests conducted over long time periods will sample large portions of the aquifer and the results will be average properties of the aquifer, including possible structural features such as faults. Short-term tests and/or tests in wells with short screens will sample small-scale features. The results from such tests will tend to show much greater variability than those in the first category. Only field-scale test results are considered here, since these are most pertinent to field-scale flow and transport in the regional aquifer. Borehole geophysics and bench-scale test approaches to

estimating hydraulic conductivity are not summarized here, although borehole geophysics-based estimates of effective porosity are discussed.

2.4.2.1 Expected Lithologic Controls on Regional Aquifer Hydrologic Properties

The two major types of aquifer rocks beneath the Pajario Plateau are sedimentary and volcanic rocks. The hydrologic properties of sedimentary and volcanic rocks can be very different and they are discussed separately.

Sedimentary units include the Puye Formation, pumice-rich volcaniclastic rocks, Totavi Lentil, older fanglomerate, Santa Fe Group sands, and sedimentary deposits between basalt flows. Based on outcrop and borehole observations, all these units are expected to be highly heterogeneous and strongly anisotropic, with a much higher conductivity parallel to sedimentary beds than perpendicular to these beds. Figure 2-21 shows photographs of the Puye Formation and the Santa Fe Group showing the typical nature of bedding. Figure 2-22 shows an outcrop of the Totavi Lentil, a unit found at the base of the Puye in some locations, containing cobble beds with abundant quartzite.

The Puye Formation is heterogeneous, containing a variety of sedimentary lithologies. Based on previous studies by Waresback et al. (1984) and Turbeville (1991) significant heterogeneity is expected to occur at scales from kilometers to meters (laterally) and meters to centimeters (vertically).

Due to lack of drill core, it is generally not possible to identify the depositional environments penetrated by R-wells within the Puye. Cuttings and borehole geophysics were used to distinguish between Puye fanglomerate (dacite detritius and sparse to absent pumice fragments), pumice-rich volcaniclastic rocks (abundant pumiceous fragments), Totavi Lentil (rounded clasts of abundant quartzite and other Precambrian lithologies), and older fanglomerate (volcanic detritus and sparse quartzite). The pumic-rich volcaniclastic rocks are expected to have a relatively high porosity, given the abundance of fairly coarse vitric pumice fragments. This high porosity *may* translate to high permeability. In some areas the pumiceous rocks are extensively clay-altered and permeability may be greatly reduced. The Totavi Lentil, an ancestral Rio-Grande alluvial deposit, is possibly the most transmissive of the sedimentary units due to the abundance of unconsolidated sands and gravels (see Figure 2-22). Fine-grained sediments, which may have low permeability, are also present in this unit.

Purtymun (1995) identified a thick zone of highly productive aquifer rocks that extends northeastward across the central plateau. Recent revisions to the plateau stratigraphy (Section 2.1) suggest that this zone includes older fanglomerate deposits, pumiceous volcaniclastic rocks, and lower portions of the Puye Formation. As will be shown below, both high and low permeability rocks are present within this zone.

Figure 2-21. (a) Outcrop of the Puye Formation, Rendija Canyon (north of LANL); (b) Outcrop of the Santa Fe Group, lower Los Alamos Canyon (east of LANL); (c) Outcrop of the Santa Fe Group, near Española (provided by Gary Smith, UNM Dept. of Earth and Planetary Sciences).

Figure 2-22. Outcrop of Totavi Lentil along SR 304 (D. Vaniman in foreground).

In heterogeneous units like these sedimentary deposits, it is particularly important to determine the lateral continuity of the high-permeability facies such as coarse stream channel deposits. However, it has not been possible to correlate individual beds in the Puye Formation because channel and overbank deposits in alluvial fan settings form complex, cross-cutting deposits, many of which are channelized or of limited lateral extent. Because of similar source rocks, clast compositions fail to provide distinct criteria for discriminating individual beds, particularly for boreholes spaced as far apart as the R-wells.

The storage properties of these rocks are expected to be within the normal range for sedimentary aquifers: specific yield (Sy) between 0.01 and 0.3 and storativity (S) between 5.E-3 and 5E-5. Likewise, effective porosity values are expected to be in the normal range for sedimentary rocks from 0.1 to 0.3 (Freeze and Cherry, 1979).

Volcanic rocks on the Pajarito Plateau include intermediate-composition lavas of the Tschicoma Formation and basalts (Cerros del Rio, Bayo Canyon, and Miocene basalts within the Santa Fe Group). These volcanic rocks consist of stacked lava flows separated by interflow zones. Figure 2-23 shows an example of Cerros del Rio basalt. Flow interiors are made up of dense impermeable rock that is variably fractured. The interflow zones contain highly porous breccias, clinker, cinder deposits, and sedimentary deposits. Groundwater flow in lava interiors is controlled by fractures, with hydraulic conductivity determined by aperture dimensions, fracture density, interconnectivity, and the presence or absence of fracture-filling minerals. Porous flow is expected to dominate groundwater flow in the interflow zones. Both nonfractured flow interiors and clay-filled fractured zones are expected to have very low permeability; zones with significant, connected open fractures, lava tubes, and interflow zones are expected to have higher permeability and low porosity, a combination of properties which can lead to very fast travel times (Stauffer and Stone, 2005).

The lava interiors presumably have very low effective porosity (<<0.1) and negligible storativity. Highly fractured zones and interflow zones may have larger porosity and storativity values, comparable to values expected for sedimentary rocks. Moderately fractured zones may have low effective porosity (10^{-3}–10^{-4}). Table 2-2 summarizes qualitative expectations of aquifer properties based on lithology and on the available data, augmented by field-scale testing, model calibration, and head gradients.

Fault zones. There are several faults on the plateau, including the Pajarito fault zone and the Rendija Canyon and Guaje Canyon faults (Figure 2-2). These are primarily oriented north-south, with local deviations. There are numerous north-south trending faults in the Santa Fe Group within the larger Española Basin; these types of faults are presumably present beneath the plateau, but they are covered by younger rocks. In general, faults can be conduits to flow (if open) or barriers to flow (if cemented or clay-filled). Field hydrologic evidence has been interpreted based on both of these occurrences. For example, Griggs and Hem (1964) postulated the presence of a fault acting as a flow barrier based on pumping tests in the Guaje Canyon wells. By contrast, Purtymun (1977) and Blake et al. (1995) observed evidence of faults acting as conduits for upward flow of deep thermal waters in the Santa Fe Group, based on geochemical and thermal evidence in lower Los Alamos Canyon wells and San Ildefonso wells. More recently, Keating et al. (2003), suggested that the large-scale effective permeability of the

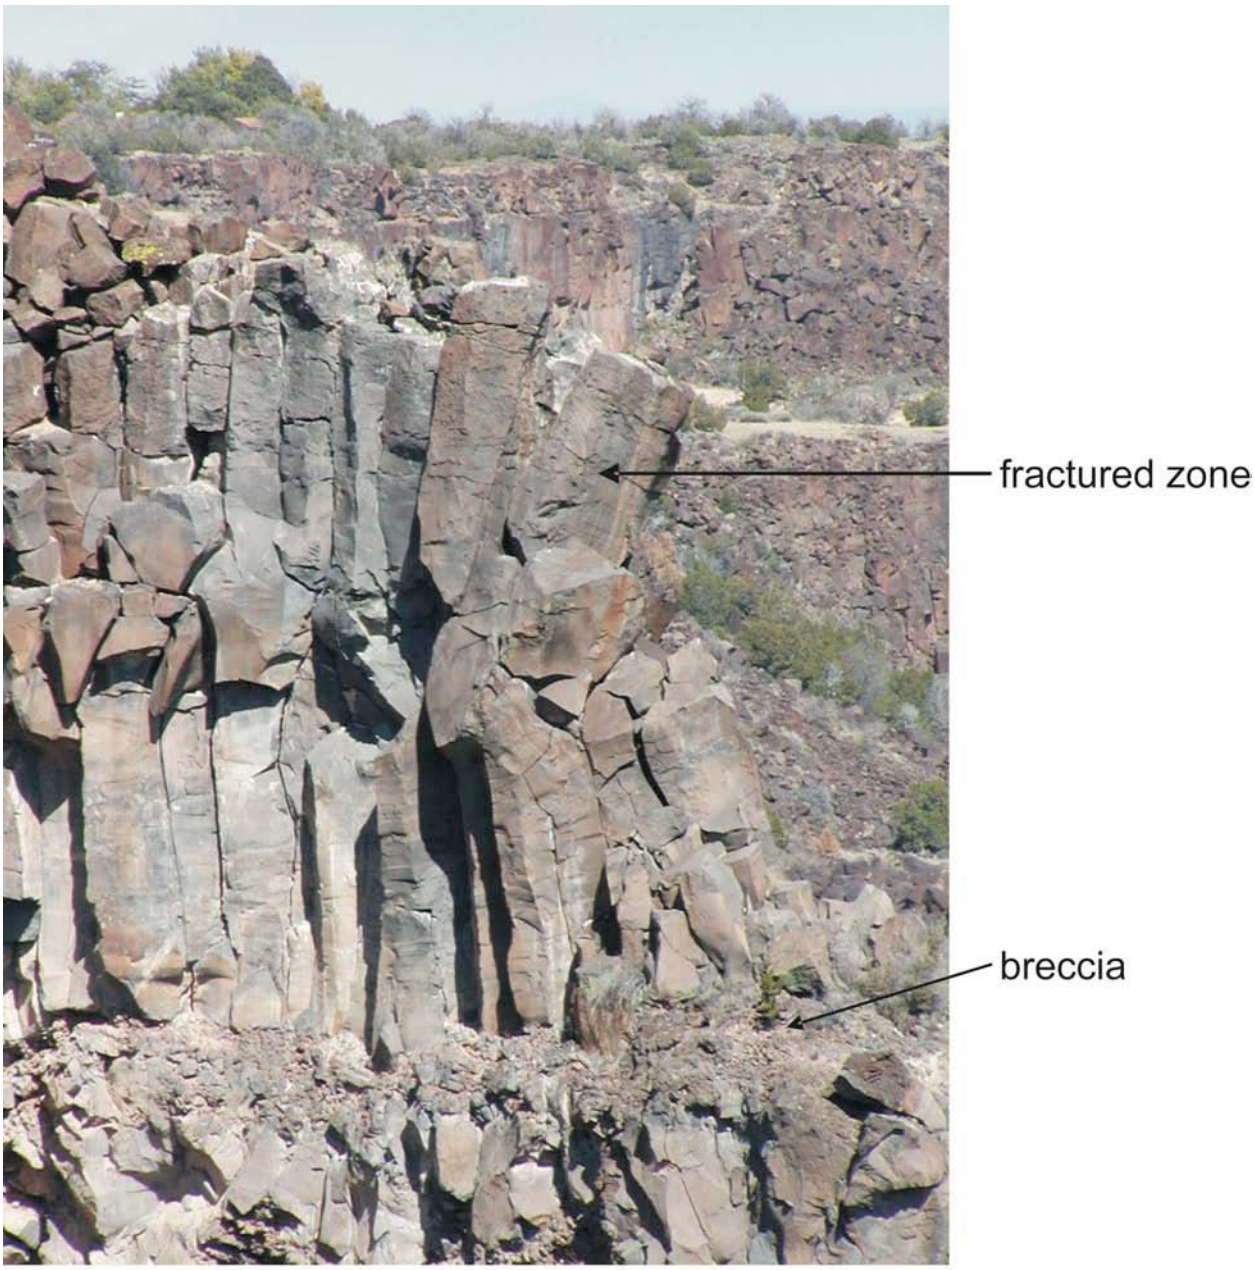

Figure 2-23. Outcrop of Cerros del Rio basalt at White Rock Overlook (east of LANL).

Table 2-2.
Inferred Properties of Hydrostratigraphic Units, Based on Field-Scale Testing, Model Calibration, and Head Gradients

Stratigraphic Unit	Sub-Unit	Description	Hydraulic Conductivity	Effective Porosity	Storage
Puye	Fanglomerate	Stream channel, overbank, colluvium, and lahar deposits	Extremely variable(0.007–45 m/day), both the highest and lowest K estimates on the plateau occur within this unit	0.07–0.2	No data
	Pumiceous	Ash and pumice-rich layers, both air fall and reworked	Extremely variable (0.3–6 m/day)	0.15–0 .2	No data
Lava flows (Tb1, Tb2, Tb4, Tt)	Massive	Pore space (vesicles) is not connected	<0.15 m/day	No data	No data
	Fractured	In flow interiors, fractures tend to be vertical; near flow tops and bottoms, many fracture orientations are observed, including sub-horizontal	1–9 m/day	No data	No data
	Breccia zones	Highly fractured rock, either open or clay-filled	No data	No data	No data
Santa Fe Group	Sandy	Alluvial fan deposits (stream channel, colluvium, overbank)	Relatively uniform (0.3 m/day); faults may decrease large scale effective K	No data	Log10 [m_{-1}] ~ –3.8 to–4.8
	Fanglomerate	Stream channel, overbank, and colluvium,	Variable (0.1–5.3 m/day), no evidence of very high permeability	No data	Log10 [m_{-1}] ~ –5.5

Pajarito fault zone is lower than surrounding rocks, based on observations of large horizontal gradients and model interpretations of these gradients. They also concluded that the large-scale effective permeability of the Santa Fe Group is lower than that indicated by individual pump test results (summarized below). These results indicate that faults in the Santa Fe Group, which tend to be north-south trending (transverse to the hydraulic gradient), may act as flow barriers in the direction perpendicular to their orientation, lowering the large-scale effective permeability of the aquifer.

2.4.2.2 Contact between Units

Depths to contacts between the major geologic units are generally well established, but their physical characteristics must be inferred from cuttings and geophysical logs. Outcrop data provide additional information about these contacts. Intra-formational and between-unit sedimentary contacts are generally conformable but are frequently disrupted by facies transitions and channel incisions. Individual beds can be traced laterally over the scale of meters to hundreds of meters. Major erosional unconformities between principal units, such as the Puye and Tesuque Formations, probably occur beneath the Pajarito Plateau, but the nature and orientations of features such as paleocanyons are unknown. Features such as clay-rich soils occur internally within some units like the Puye Formation, but do not appear to be important along intraformational contacts.

The contacts between coarse-grained units, such as the Puye Formation or the older fanglomerate, and fine-grained sediments of the Tesuque Formation may have hydrologic significance because of the juxtaposition of fundamentally different lithologies. Where exposed in the eastern part of the plateau, the contact between Puye rocks and Tesuque strata is a slight angular unconformity. Hydraulic gradients are generally easterly/southeasterly on the plateau (Figure 2-24). Within the Puye Formation, this driving force is parallel to the east-dipping beds. In contrast, within the Tesuque Formation, beds tilt to the west. This anisotropic condition will result in larger flow resistance and possible local deviations in flow direction within the Tesuque rocks.

The contact between the older fanglomerate and the Tesuque Formation may also be hydrologically important. In Guaje Canyon, thick sequences of older fanglomerate interfinger laterally for several kilometers with the Tesuque Formation (see Griggs, 1964 for discussion of these relations). The effect of these interfingering relations on groundwater flow is not known but could include changes in potentiometric surface gradients and partial confinement of groundwater in older fanglomerate enclosed by less permeable Tesuque strata. In Los Alamos and Pueblo Canyons, lateral infingering between the older fanglomerate and the Tesuque Formation appears to be more abrupt. The lithologic difference between the older fanglomerate in Otowi-4 and the Tesuque Formation in Otowi-1 is striking, and the lateral hydraulic conductivity should decrease eastward. The presence of altered Miocene basalts in the Tesuque Formation in wells R-9 and R-12 should also contribute to a decrease in hydraulic conductivity eastward.

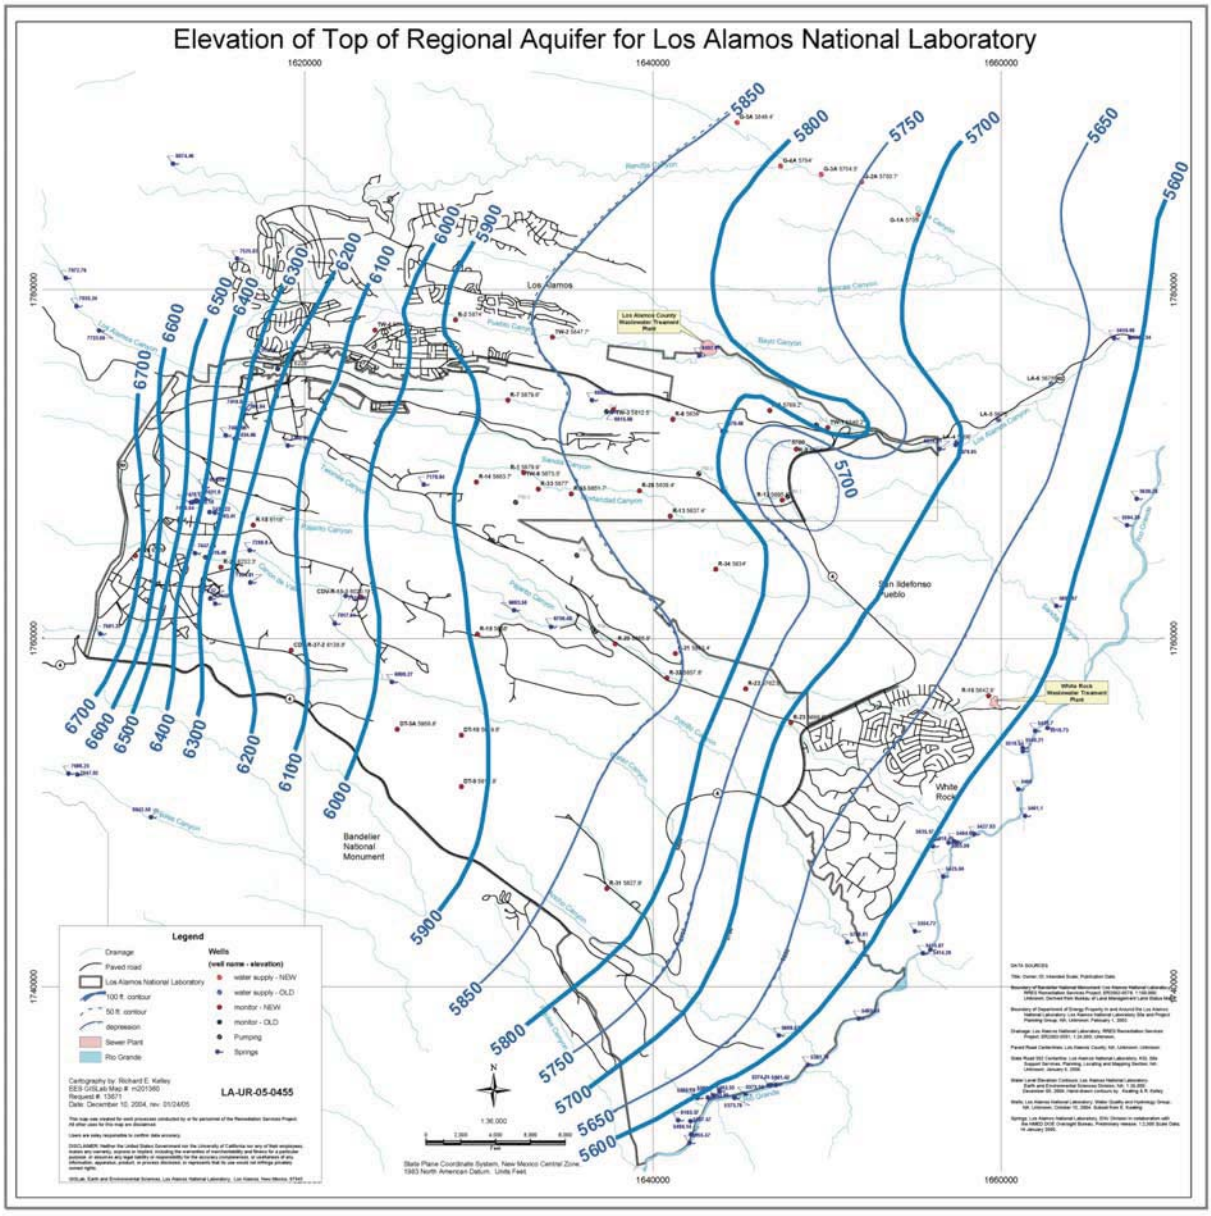

Figure 2-24. Regional aquifer water table map.

We note again that the sedimentary rocks themselves are highly stratified, and so contrasts between layers within these rocks may be as hydrologically significant (or more so) than the contacts between major geologic units described above. Contacts within volcanic units can have significant hydrologic impact. The contacts between lava flows are generally represented by interflow zones that can be very transmissive or, if clay-filled, barriers to flow. One example of a low-permeability, clay-filled interflow zone was that encountered in screen 2 of R-9i. This zone appears to act as a confining bed; water levels rose significantly in the borehole after the well penetrated this zone. Contacts between sedimentary and volcanic rocks can be structurally complex, as in the inferred paleovalley in the eastern part of the plateau that is filled by Cerros

del Rio basalt (Section 2.2.8; Figure 2-8). Groundwater flow from west to east may be more tortuous and possibly diverted when encountering such large-scale structures.

2.4.2.3 Regional Aquifer Hydraulic Conductivity

Inferences based on field-scale testing. Over the last 40 years, hydraulic conductivity has been measured using pump tests and straddle-packer injection tests in 61 locations within the Pajarito Plateau; some locations have been measured multiple times. Table 2-3 presents a compilation of these test results (86 in all). For those wells tested multiple times, or for which multiple interpretations of a single test are available, we selected one representative value for the discussion and analyses below (these are indicated with an asterisk in Table 2-3). All these tests are within the regional aquifer, with the exception of a perched zone in R-9i that is included because it represents a test of saturated basalt. If the screened interval for a test contained at least 50% of a single stratigraphic unit, the test was categorized as representing that unit. Some wells (all the PM wells, for example) are screened across too many rock units and are labeled as "mixed" in Table 2-3.

Figure 2-25 shows a histogram of the 61 hydraulic conductivity values, which range from 0.007 m/day (R-26, screen 2) to 45 m/day (R-28). The geometric mean of these estimates is 0.6 m/day, and the distribution appears to be lognormal, although we ascribe no special significance to this fact, other than to point out that it is a convenient distribution for modeling purposes. Based on the distribution, the standard deviation of the lognormal distribution is 0.76 in units of ln(m/d).

Figure 2-26 illustrates the spatial variation in hydraulic conductivity on the plateau. There are two areas with relatively high hydraulic conductivity ($K > 3$ m/day): the north-central aquifer beneath LANL (TW-2, R-4, TW-3, R-11, R-28, and R-13) and the south-central aquifer beneath LANL (R-19, screen 6, DT-10, DT-9). The location of these zones overlaps the zone of high-yield wells identified by Purtymun (1984). However, based on new geologic data and interpretations, the rocks making up this zone consist of a variety of sedimentary and volcanic units in addition to those attributed to the "Chaquehui Formation" by Purtymun. Also, it is clear that lower conductivity zones also exist within Purtymun's proposed northeast-trending high-production trough, indicating that it is a heterogeneous portion of the aquifer, with locally high and low permeability zones.

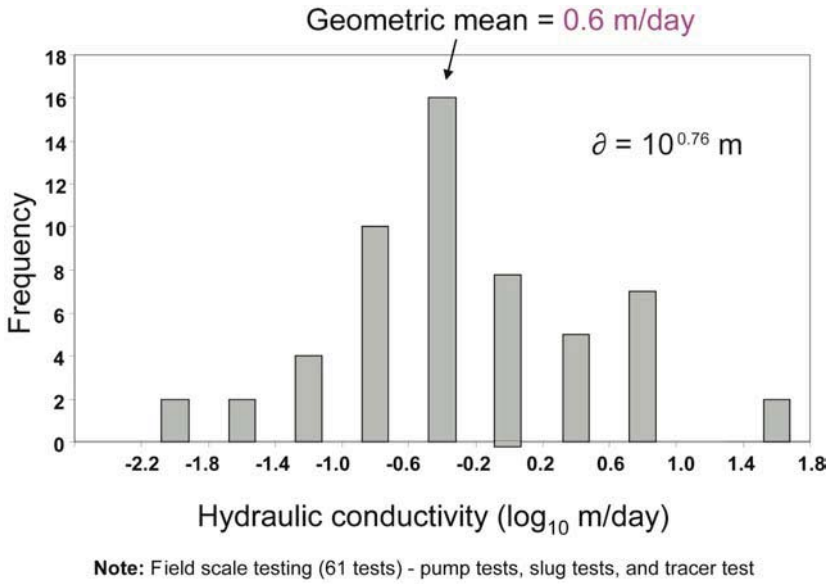

Figure 2-25. Distribution of hydraulic conductivity estimates, derived from tests of 59 wells on the plateau; N = 59; geometric mean = 0.6 m/day.

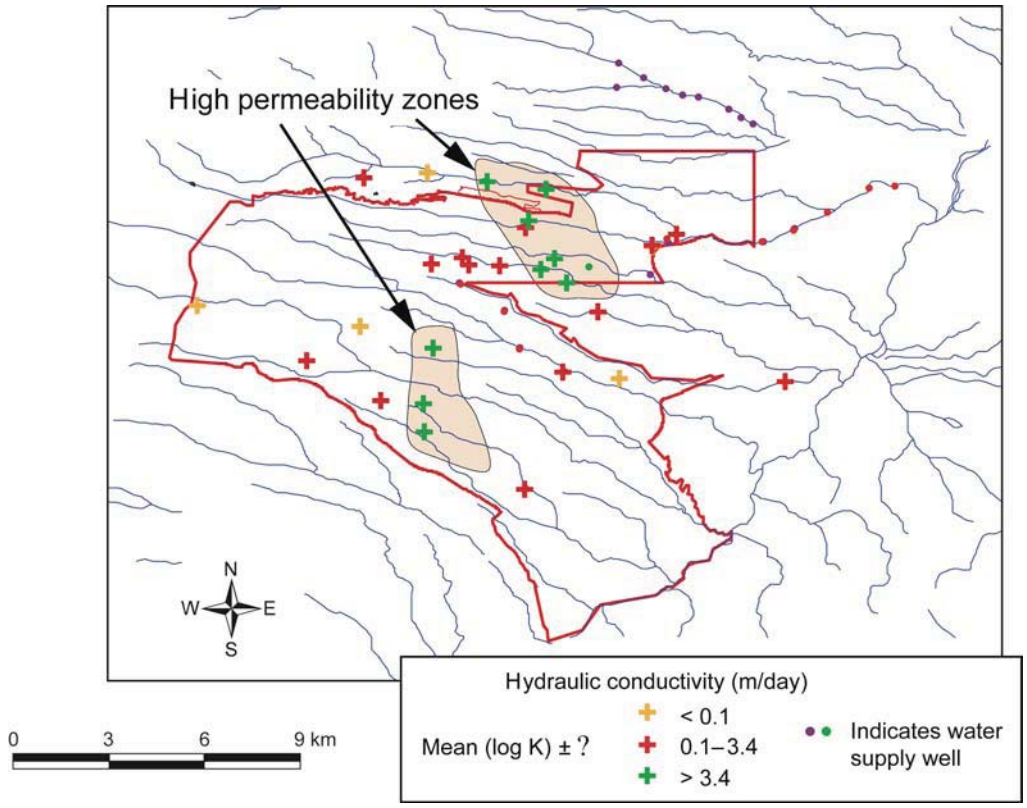

Figure 2-26. Hydraulic conductivity estimates in the regional aquifer. If multiple screens have been tested at a single location, the uppermost result is shown. Red line is the outline of the Laboratory.

In several wells there are multiple estimates of hydraulic conductivity at different depths (R-22, CDV-R-15-3, CDV-R-37-2, R-16, R-31, R-19, R-9i); in these cases we show the uppermost screen result in Figure 2-26. Only two of these wells, R-9i and R-31, show significant difference in hydraulic conductivity with depth. R-31, screen 3 (uppermost regional aquifer screen), completed in basalt, is very poorly conductive. The two lower screens, 4 and 5, completed in the Totavi Lentil, are very conductive. For this reason, they are shown in Figure 2-26 as connected to the southern high permeability zone. Both screens in R-9i are completed in basalt. The upper conductive screen is located in an interval that includes highly fractured basalt and an interflow zone, and the lower nonconductive screen is located within clay-filled interflow breccia at the base of the basalt sequence. The other wells (R-22, CDV-R-15-3, CDV-R-37-2, and R-19) show consistent results in all screens. This is particularly interesting in the case of R-22 and CDV-R-15-3, where the screens are located in a variety of rock units.

The hydraulic conductivity values for major rock units of the regional aquifer are shown in Figure 2-27 and summarized in Table 2-4. Cerros del Rio basalt, Puye Formation, pumiceous volcaniclastic rocks, Totavi Lentil, older fanglomerate, and Santa Fe Group sands are clearly heterogeneous. The Santa Fe Group sandy unit (Tesuque Formation) appears to be more uniform, although many of the wells representing this unit have very long screens (>300 m), which would tend to smooth the effect of small-scale heterogeneity. Nonetheless, the short screens within Tesuque sands tested at R-16 gave results similar to those obtained from wells with long screens.

The variation within the Cerros del Rio basalt may be related to whether the tested interval contains abundant open fractures (as reported at R-9i, screen 1) or is a clay-filled interflow zone (reported at R-9i, screen 2). All three tests within the Tschicoma Formation represent interflow zones and/or breccia and show relatively high permeability. Both outcrop and borehole observations suggest that much of the Tschicoma Formation is, in fact, massive and so these tests of breccia zones may not be representative of the larger aquifer unit. Some of the low permeability measurements in the Cerros del Rio basalt may represent clay-filled fractures in flow interiors or clay-filled interflow breccia zones.

A number of factors could explain the variability of hydraulic conductivities within the Puye, the Totavi, and the Santa Fe Group fanglomerate, including different degrees of alteration (clay content) and intraformational depositional facies (e.g., stream channel versus overbank deposits). Depositional facies are characterized by different grain sizes and degrees of sorting, but bedding characteristics and rock fabric are needed to evaluate the depositional setting. Bedding and rock fabric cannot be identified from drill cuttings, however borehole geophysical tools such as FMI logs can provide information that may be relevant (Table 2-5). In some cases, depositional environments inferred from FMI logs (Table 2-5) appear to be related to measured hydraulic conductivities. For example, the coarse-grained, poorly sorted gravels and cobbles in CdV-R-15-3, screens 5 and 6, are consistent with deposits expected in proximal alluvial fan deposits. The K values measured here (0.08 and 0.03 m/day, respectively) are lower than most on the plateau. The four highest conductivity zones in Tpf or Tpp, measured in R-28, R-11, R-4, and R-13, are associated with well-bedded sands and gravels with sparse cobbles located in the medial portion of the Puye alluvial fans. Fractures are visible in the screened intervals of the R-11 and R-13 wells.

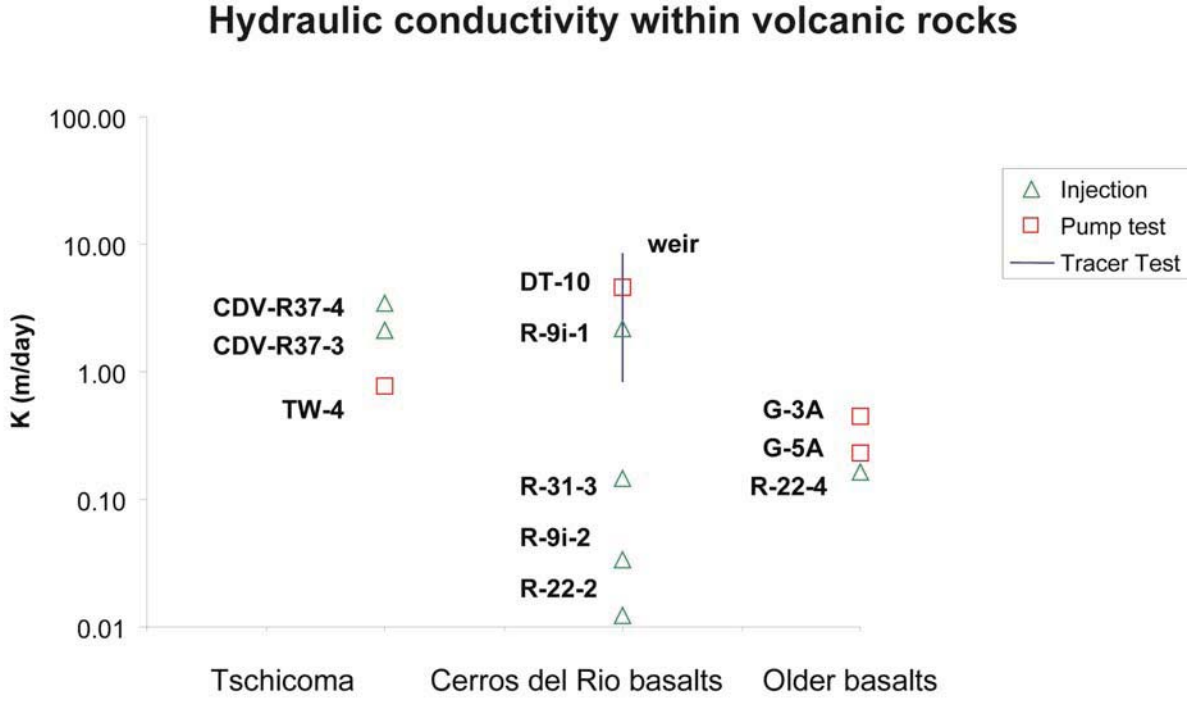

Figure 2-27-b. Variation of hydraulic conductivity in volcanic rocks of the Pajarito Plateau.

Table 2-4.
Summary Table of Hydraulic Conductivity for Each Hydrostratigraphic Unit

Unit		Number of Wells	m/day	Max m/day	Geometric Mean
Cerros del Rio		5	<0.1	4.5	0.2
	Older	3	0.2	0.6	0.3
Puye	fanglomerate	6	.007	45	0.4
	pumiceous	9	0.3	36	1.3
Totavi		5	0.2	9.8	2.1
Santa Fe Group	Fanglomerate	5	0.1	5.3	0.4
	Sandy	18	0.2	0.5	0.3
	(off plateau data)*	15	<0.1	4.4	0.1
Tschicoma		3	0.2	9.8	0.9

Source: Daniel B. Stephens (1994)
Note: An asterisk (*) means reported in the literature by numerous workers.

There are exceptions to these trends, however. For example, screen 3 of R-32 is also completed in the medial portion of Puye Formation alluvial fans, but has lower conductivities than the wells listed above. The screened interval in R-28 does not show evidence of fractures, yet it has a higher conductivity than does R-11, which is screened across an interval containing several fractures.

The possible influence of alteration can be examined by comparing the percentage of clay present in a hydrostratigraphic unit to the spatial variation in permeability. As shown in Figure 2-28a, there is a tendency for the Puye Formation and pumice-rich volcaniclastic rocks to be more altered in the southeastern portion of the plateau, which may explain the low K values estimated for R-22, screen 3 and R-32, screen 3. However, low clay content is not necessarily associated with higher conductivity. R-26, screen 2 in the western part of the plateau has low clay content and a low K value. Presumably a combination of facies distributions and post-depositional alteration are contributing to the complex patterns evident in Figure 2-26. Data on which to base these results are somewhat limited, and additional data collection could shed light on this issue.

There is no readily apparent correlation between alteration trends in the pumiceous unit (Figure 2-28b) and hydraulic conductivity. In fact, the lowest K values reported for this unit (CDV-R-15-3, screen 6, and R-14, screen 2) are both in regions of lowest clay content. With the limited data available, it appears that alteration within the pumiceous unit is not the only factor controlling hydraulic conductivity.

Table 2-5.
Summary of Formation Micro-Image (FMI) Data Derived from Borehole Geophysics

Drillhole	K m/day	Unit	Texture	Bed thickness	Orientation	Fractures	Effective porosity	Comments
R-26	0.002	Tpf	Very coarse, crude bedding, boulders 2 ft tall	Most are 5–10 ft (some are 0.5 ft)	10–40^{o}	nd	2–0%	Similar to outcrops in upper Guaje, vertical k should be large, probably is colluvium (like at the bottom of a fault scarp)
CDV-R15-3-5	nd	nd	Discrete packages of coarse and fine layers, 1520% is boulder beds, rest is sand and gravels, perhaps thin clay beds, overlapping channel deposits and some overbank	1–5 ft (sand beds are 1 ft)	nd	nd	nd	Coarse layers are comparable to R-26
CDV-R15-3-6	nd	nd	Coarser than screen 5, mostly discrete sand bodies (above screen in sandpack are gravel and coarse sands)	0.5–5 ft	nd	nd	nd	Similar to outcrops in upper Rendija Canyon
R-13	17.6	Tpf (upper half of screen)	Sand and gravel beds, a few cobbley lenses	1 ft–3 ft	nd	One 8' vertical, another dipping, intersecting 2 ft of screen	>60%	Medial fan
	nd	Tpp (upper half of screen)	Fine bedding, intercolated in coarser beds of gravels and cobbles	2-6 in.	nd	nd	nd	
R-11	116.5	Tpp	No fine-grained beds, very stratified	0.5 ft (up to 3 ft)	<10^{o}	Fractures visible (one 2 ft long)	5–10%	
R-28	149	Tpf	Very similar to R-11, very stratified, perhaps can correlate beds	nd	5–10^{o} (S and E)	None visible	15–60%	

Table 2-5.
Summary of Formation Micro-Image (FMI) Data Derived from Borehole Geophysics (continued)

Drillhole	K m/day	Unit	Texture	Bed thickness	Orientation	Fractures	Effective porosity	Comments
R-4	17.4	Tf	Mostly sands and gravels, very sparse cobbles, very stratified	Few tenths up to 1 ft	5–0° (30° max)	nd		
R-2	0.31	Tf	Coarser, 15% cobbles, the rest is sand and gravels	Most are 1–2 ft (range 0.5–3 ft)	Many dips are to the west	nd	5–10%	
R-16-2	1.6	Tsf	Sands and silts, a little gravel (10% or less)	0.1–1.5 ft	2–10° variable direction	nd	nd	
R-16-3	1.8	Tsf	Sands and silts, sand beds are massive (2' thick)	nd	10–5° dip, strongly westerly	nd	nd	
R-16-4	1.7	Tsf	Fine laminar bedding, silts sands, perhaps some cross-bedding	0.1 ft or less (max of 0.5 ft)	10–0° (to the west)	nd	nd	
R-34	3.5	Tpp	Fairly coarse, gravels with some cobble beds, lesser amount of sand	Mostly 3 ft (0.5 to 4 ft)	Not many data, 5–10°	Most commonly 35% (10–60)	nd	Pumice looks mostly reworked, possibly one fall bed

Note: nd = no data

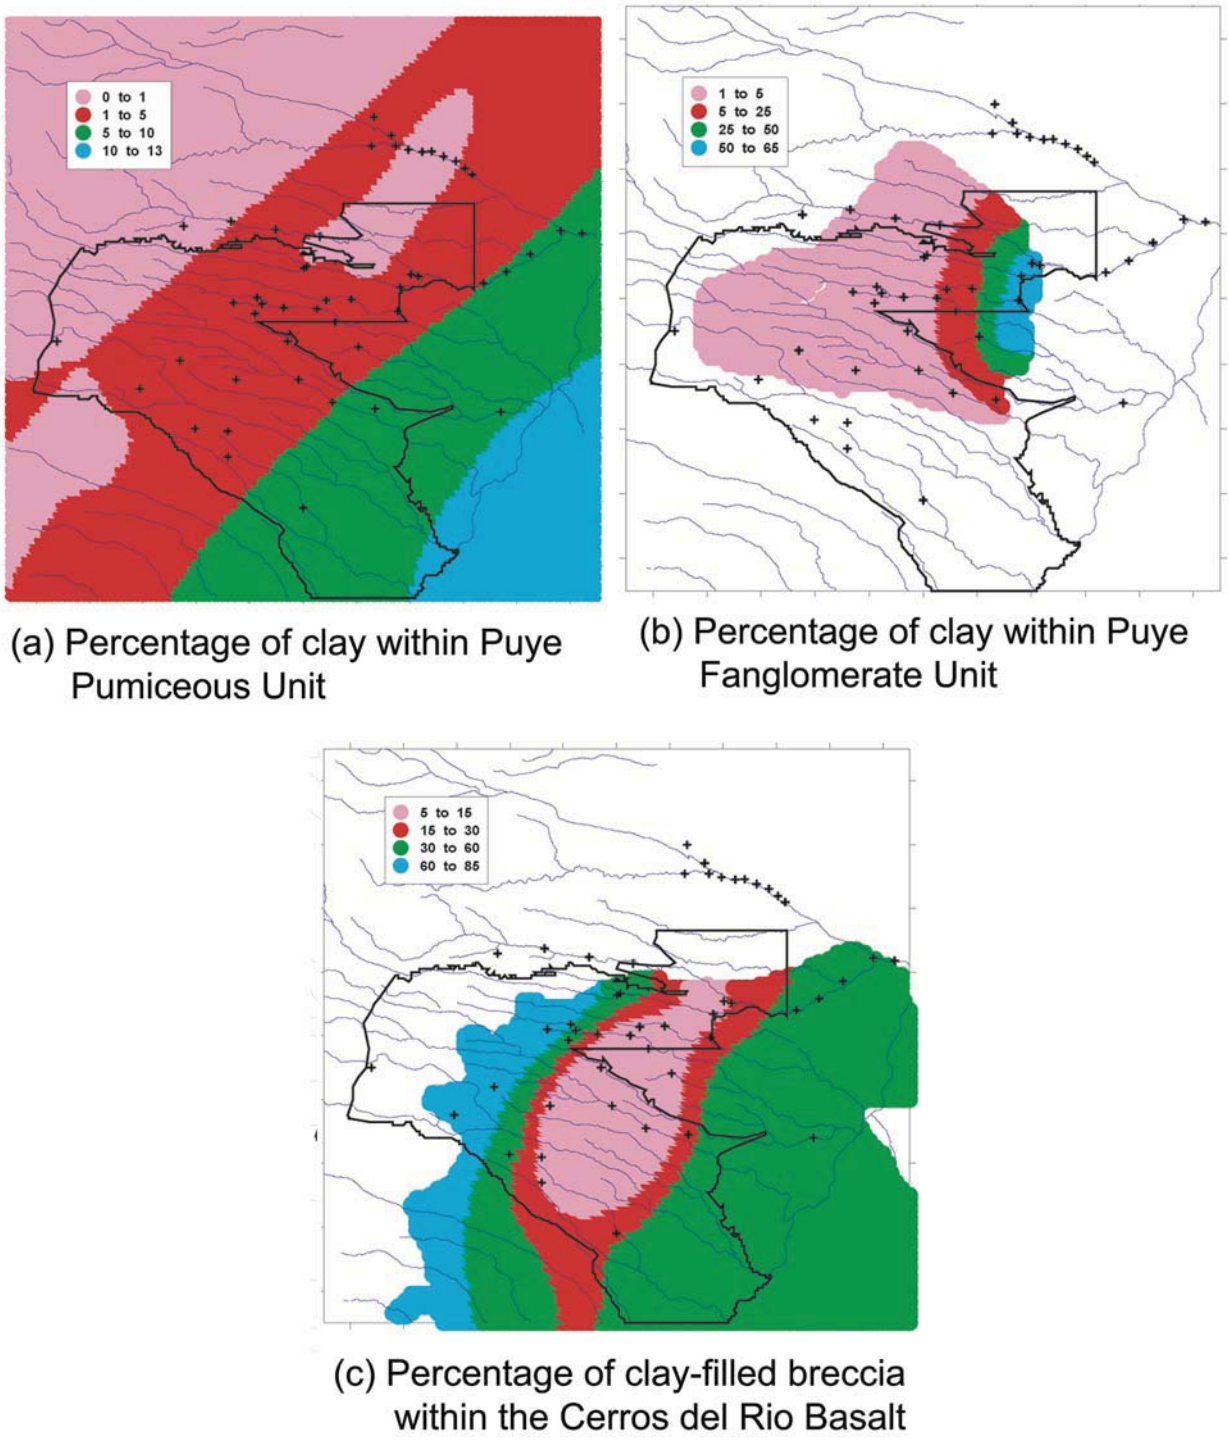

Figure 2-28. Comparison of the percentage of clay present in a hydrostratigraphic unit to the spatial variation in permeability: (a) percentage of clay within the Puye pumiceous unit; (b) percentage of clay within Puye fanglomerate unit; (c) percentage of clay-filled breccia within the Cerros del Rio basalt.
Note: + = well locations

The percent of clay-filled breccia within the Cerros del Rio basalts (Figure 2-28c) is relatively high to the southeast and this factor may explain the low K value estimated for R-22, screen 2 and R-31, screen 3. These areas coincide with the topographically-highest part of the Cerros del Rio basalts on the Pajarito Plateau, and they probably are proximal volcanic vent areas. The low values for K and high degrees of alteration here, both within the basalts and within the Puye, suggest that hydrothermal alteration may have affected the rocks in this area.

Despite the evident variability in most of the rock types, the average properties of the rocks derived from our limited data sets show a few distinctions. The geometric mean hydraulic conductivity of the pumice-rich unit and Totavi Lentil appear to be significantly greater than the other rock types (Table 2-4). At large scales, this trend may be important for flow and transport calculations. At small scales, however, the variability evident in both these rock types will be very important to consider. Local flow directions in the vicinity of release locations and water supply wells are likely to depend strongly on these small-scale differences in hydrologic properties.

Inferences based on hydraulic gradients. Head gradients will tend to be larger in low permeability rocks, and so head data can be used, at least in a qualitative way, to infer information about permeability. Other controls on head gradients, such a recharge and pumping, complicate this approach. It is evident from the water table map (Figure 2-24) that there is large spatial variation in head gradients at the top of the aquifer. If these variations were entirely or mostly due to variations in permeability, we might conclude that rocks and structures on the western portion of the plateau (Tschicoma Formation, Pajarito Fault zone) have relatively low permeability. However, mountain-front recharge creates hydrologic conditions that lead to larger gradients, even if the rocks were homogeneous. In addition, there is an increase in permeability towards the center of the plateau (older fanglomerate, pumiceous rocks, Puye Formation and Cerros del Rio basalts). The gradient is relatively steep in the vicinity of R-22, where hydraulic testing indicates very low permeability (locally) in the Cerros del Rio basalts.

2.4.2.4 Anisotropy

As mentioned above, bedding within the Santa Fe Group and the Puye Formation is likely to cause higher permeability parallel to beds than perpendicular to beds. Large vertical head gradients measured in R wells are evidence of anisotropy; persistent vertical gradients are presumably caused by intermittent low-permeability strata that provide resistance to vertical flow. The beds within the Puye Formation range from centimeters to meters in thickness. Most are very low angle, dipping to the east. In contrast, beds within the pumiceous volcaniclastic rocks tend to dip to the southwest (R-20, R-2, R-7, R-19, and R-33). Beds within the Santa Fe Group exposed on the eastern margin of the plateau dip approximately 2–5^{o} to the west (Golombek et al. 1983). Data from R-16 suggest that shallow layers are very low-angle, but deeper layers dip as much as 14^{o} to the west. Hydrologic modeling and pump test analysis suggests that vertical permeability is 100 to 1000 times lower than horizontal permeability in the Santa Fe Group silts and sands (Hearne, 1985; McAda and Wasiolek, 1988; Keating et al., 2003).

If the north-south trending fault zones on the plateau tend to be barriers to flow, this would cause horizontal anisotropy, with north-south permeability higher than east-west permeability. Multiple-well pump tests on the plateau could be used to test this hypothesis.

2.4.2.5 Porosity

Tracer tests, which provide the most valuable information about effective porosity, have not been conducted in the saturated zone at this site. The only available data come from interpretations of borehole geophysical logs, using the combined magnetic resonance (CMR) tool. Using only data from the Puye Formation and the pumice-rich volcaniclastic rocks within the saturated zone, estimates of total porosity based on geophysical logs from R-7, R-19, and CDV-R-15-3 have been compiled. Figure 2-29 shows the distribution of these estimates, with data collected at 0.5 ft intervals. Table 2-6 summarizes the data. The mean effective porosity for these units as estimated from these logs (0.01–0.2) are somewhat low for sedimentary rocks (0.1–0.3, from Freeze and Cherry 1979). There is some indication that these values relate to hydraulic conductivity. For example, CDV-R-15, which has a high proportion of very low effective porosity measurements, also has a relatively low hydraulic conductivity (0.03–0.08 m/day; Table 2-6). R-19 has higher mean effective porosities and higher K values (5.7–6.7 m/day). However, there are significant differences in effective porosities between screens 5 and 6 in CDV-R-15 that do not correlate with differences in hydraulic conductivity.

Table 2-6.
Summary of Effective Porosity Estimates based on Borehole Geophysics

Well	Mean Effective Porosity	N	Formation	Hydraulic Conductivity (m/day)
CDV-R-15[a]	0.07	744	Tpf, Tpp	-
CDV-R-15-4	0.06	87	Tpf	-
CDV-R-15-5	0.01	13	Tpf	0.08
CDV-R-15-6	0.16	15	Tpp	0.03
R19[a]	0.1	1466	Tpf, Tpp	-
R19-6	0.2	14	Tpp	5.7
R19-7	0.2	15	Tpp	6.7
R7[a]	0.09	293	Tpf, Tpp	-

[a] all depths within Puye Formation
Note: - = no data
Note: For comparison, hydraulic conductivity values derived from in situ testing (Table 2-3) are also shown.

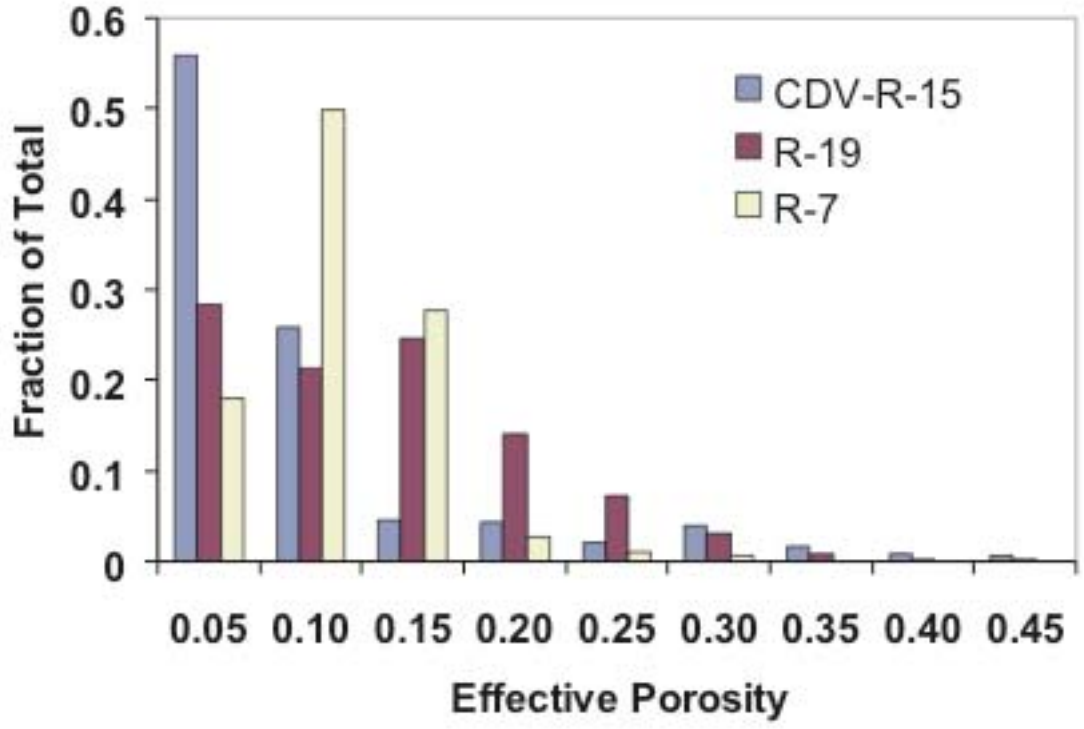

Figure 2-29. Distribution of effective porosity measured within the Puye Formation beneath the regional aquifer water table.

2.4.2.6 Storage Properties

Storage properties of rocks will depend on whether the aquifer is unconfined or confined; delineating these two conditions beneath the plateau has been difficult. There are a number of interpretations in the literature about the degree and extent of confined conditions on the Parjarito Plateau. Based on limited data, Cushman (1965) concluded that the aquifer is under water table conditions beneath the plateau, with the exception of the vicinity of the Rio Grande where water table conditions exist in shallow layers and confined conditions exist at depth. Purtymun (1974) suggested that water table conditions exist on the western margin of the plateau and artesian conditions exist along the eastern edge and along the Rio Grande. Recent drilling has confirmed the existence of water table conditions at many locations beneath the plateau. Pump test results for water supply wells, drilled to depths up to 2000 ft below the water table on the plateau, suggest that the deeper portions of the aquifer behave as either:

- "Leaky confined" in the Los Alamos well field, specific storage $S_s \sim 10^{-4.8}$/m (Theis and Conover, 1962); and in O-4, $S_s \sim 10^{-5.5}$/m (Purtymun et al., 1995a and 1995b) or
- Unconfined in O-1, $S_s \sim 10^{-3.8}$/m (Purtymun et al., 1990, Purtymun and McLin, 1990).

In the LA wellfield, Theis and Conover (1962) expanded on the "leaky confined" interpretation by stating that there are, in fact, several aquifers and several semiconfining beds in this well field. Just to the southeast, along the Rio Grande, the aquifer has been called "partially confined" (Balleau Groundwater, 1995).

Drilling activities conducted during the Hydrogeologic Workplan have shown that in most R-wells, at all screens, the aquifer is unconfined. Heads tend to decrease with depth (see Figure 2-45, Section 2.7.7). In the shallowest portion of the aquifer (the upper 150 m), specific yield is presumably dominated by effective porosity (see Table 2-6 for estimates in the Puye Formation). Specific yield is likely to be very low for basalts. No new information is available for the deeper, leaky-confined portions of the aquifer.

2.4.3 Summary of Hydrologic Properties

Pump test data (Table 2-3, Figures 2-26 and 2-27) illustrate the heterogeneity of the aquifer, with K values ranging from 0.007 to 45 m/day The geometric mean hydraulic conductivity is 0.6 m/day; the larger-scale effective permeability may be lower due to large-scale structures and/or untested, low-permeability portions of the aquifer, based on the lower permeability values obtained in regional aquifer model calibrations (Section 4.2). Table 2-2 presents a summary of inferred properties of each of the lithologies present in the regional aquifer.

Heterogeneity tends to be particularly significant in the Puye Formation, pumiceous volcaniclastic rocks, Totavi Lentil, and older fanglomerate. The wide variety of depositional environments within the Puye Formation are consistent with this observation. However, it is difficult to go beyond this general statement to develop a predictive relationship between facies and hydrologic properties. On average, the permeabilities of the Puye Formation, pumiceous volcaniclastic rocks, Totavi Lentil, and older fanglomerate are similar and ranges of permeability overlap one another.

As shown in Figure 2-26, there appear to be two zones near the top of the aquifer that are particularly conductive (>3 m/day). These zones are not correlated with hydrostratigraphy, suggesting that structure or alteration may be the controlling factor. No high permeability zones occur east of R-13. Large-scale trends in alteration (Figure 2-28) do not explain the location of these zones; although alteration may be an important factor in the location of a low-conductivity zone in the southeast (R-31 and R-22).

The older fanglomerate unit is also heterogeneous, consistent with its probable depositional history. The Tesuque sandy unit appears to be less heterogeneous, due to the dominance of relatively well-sorted sand and silt layers (Section 2.2.1). Discrepancies between pump test data and model-calibrated values suggest the possibility that large-scale structures such as north-south trending faults may lower the large-scale effective permeability of this unit.

Permeabilities of volcanic rocks appear to be bimodal, presumably a function of whether the groundwater is associated with fractures in flow interiors or is found in interflow zones between lavas. The amount of clay filling pore space in these settings can also affect permeability. Permeabilities of the fractured Tschicoma and Cerros del Rio lava flows are of the order of 1 to 9 m/day; permeability of poorly fractured flow interiors or clay-filled fractured units is much lower (<0.15 m/day). Limited data on Bayo Canyon basalts suggest an intermediate permeability.

Based on the depositional environment (Figure 2-21) of the Puye Formation and the Santa Fe Group, strong anisotropy (horizontal K >> vertical K) is predicted. This is confirmed by modeling studies, pump test analyses, and by the presence of large vertical gradients in many R-wells. The ratio of horizontal to vertical K may be as large as 1000 (see Section 2.4.2.3). If north-south trending low-permeability faults exist within these units (as modeling results suggest; Keating et al., 2003), this would tend to cause horizontal anisotropy.

Although porosity data are limited, geophysical logs indicate that the effective porosity of the sedimentary rocks is relatively low (0.07–0.2). Small-scale data from these geophysical logs need to be augmented by interwell tracer tests to obtain larger scale, transport-related porosity values that can be used in numerical models and transport-velocity estimates.

2.4.4 Uncertainties in the Relationship between Geologic and Hydrogeologic Units

This section describes uncertainties and sources of error in defining the relationships between hydrogeologic properties and lithology. Three of the uncertainties described here are large scale, in that they reflect the reliability of stratigraphic assignments. The large-scale uncertainties are:

- Extent and hydrogeologic nature of the Cerros del Rio unit
- Unassigned pumiceous sediments of uncertain age
- Totavi variants (see Section 2.4.4.3 below)

The remaining two uncertainties are small scale, in that they address uncertainties in the composition within a single stratigraphic unit or of a single property. The small-scale uncertainties are:

- Disposition of Santa Fe Group sediments
- Spatial variation in permeability within sedimentary rocks

2.4.4.1 Extent and Nature of the Cerros del Rio Hydrogeologic Unit

The Cerros del Rio hydrogeologic unit straddles the top of regional saturation across much of the southeastern portion of the LANL site (Figure 2-10). The thickness of the unit has proved difficult to predict in critical areas (e.g., drillhole R-22 within TA-54) because multiple flows from different source areas accumulated as stacked sequences in topographically low areas. The nature of the volcanic deposits is highly variable and has led to difficult drilling, as at R-34 where the drill site appears to have been located above a buried cinder cone with no surface expression and unknown shape and lateral extent (Figure 2-14). Data from the basalt field in the Snake River Plain indicate that permeability in basaltic volcanic sequences can vary by 10 orders of magnitude from the laboratory to the field scale, and the flow field can be strongly anisotropic (Whelan and Reed, 1997). Drilling experience in this unit at LANL shows that air permeability can be very high; open boreholes generally "breathe" with diurnal barometric variation as soon as they penetrate into the Cerros del Rio deposits. All of these features indicate significant importance of the Cerros del Rio in flow and transport. At present the 3-D geologic model allows for estimation of relative percent of flow interior, open breccia, and clay-filled breccia for each borehole, but such distributed percentages may not be sufficient for adequate hydrogeologic characterization where stochastic flow simulation may require knowledge of volcanic stratigraphy (Whelan and Reed, 1997). In addition, a conceptual model describing the characteristic length scales of the basalt subunits would also be required.

2.4.4.2 Unassigned Pumice-Rich Volcaniclastic Rocks

The extent of clay alteration in pumiceous sediments can be a critical hydrogeologic parameter, for the unaltered deposits are highly transmissive whereas local zones of extensive clay alteration transform the pumice-rich intervals into aquitards. Extensive pumiceous sediments (Figure 2-9) are widely distributed beneath Puye fanglomerates in the central portion of the LANL site. This unit is not known in outcrop and was not anticipated when drilling for the Hydrogeologic Workplan began. Radiometric dates of 6.8 and 7.5 Ma from pumice in this unit suggest a possible relationship with Peralta Tuff to the south, but petrographic variation and stratigraphic occurrence indicate that multiple volcanic sources supplied tephra to these deposits. The pumiceous sediments in R-9 and R-12 are completely altered to smectite, whereas other occurrences have little clay and are essentially unaltered. It is uncertain whether the altered and unaltered pumice units are related. This uncertainty can have considerable impact on how the pumiceous deposits are represented in cross-section for the conceptual geologic model (see Figure 2-12) and in 3-D for the numerical geologic model, as well as having an impact on flow and transport properties.

2.4.4.3 Totavi Variants

The Totavi may be an important transmissive unit at the site, providing a significant flowpath where laterally contiguous, making the treatment of this unit in the 3-D numerical geologic model particularly important. The axial deposits left by paleochannels of the Rio Grande are well defined in outcrop by their high abundance of Precambrian lithologies derived from northern sources. Dethier (1997) provides extensive data for these deposits exposed along the eastern margin of the LANL site; his definition of the Totavi notes that it contains "generally >80%

quartzite and other resistant lithologies from northern New Mexico, but clasts from the southern Sangre de Cristo range are common locally." The high quartzite abundance is distinctive. Previous conceptual models of the LANL site geology have extended these axial gravels in a continuous unit beneath the site as a horizon underlying Puye fanglomerates. More recent drilling has provided evidence of many stream gravels at varied stratigraphic levels, most with a smaller abundance of Precambrian stream gravels (generally <25% Precambrian gravel) and with more gravels from volcaniclastic sources. Furthermore, new radiometric dates on pumice-rich volcaniclastic rocks indicate that underlying river gravels are considerably older than the Totavi deposits exposed on the east side of the plateau. The construction of a Totavi unit is thus problematic, with some areas where the stream gravels are moderately extensive and other areas with isolated channels (e.g., cross-sections in Figures 2-12 and 2-13). Therefore, the representation of the Totavi unit within the geologic framework model is illustrative.

2.4.4.4 Disposition of Santa Fe Group Sediments

The impact of distinguishing different lithologies of Santa Fe Group sediments can be of hydrogeologic significance in defining the extent of more productive gravels and in construction of hydrogeologic unit boundaries. The Santa Fe Group sediments exposed in outcrop along the eastern margin of the LANL site consist of sands and lesser stream gravels, commonly with some amount of carbonate cement, that are derived predominantly from plutonic and metamorphic Precambrian sources. The 1997 conceptual geologic model for the site projected extensive amounts of Santa Fe Group sediments beneath the site that were predicted to be encountered by most drillholes deeper than ~1000–1500 ft. Furthermore, the central and most hydrologically productive zone was interpreted as consisting of deposits of equivalent age that contained more abundant volcaniclastic material. More recent drillholes have found that this deeper volcaniclastic material is predominantly of Jemez-derived lithologies and is distinct from the generally arkosic deposits of the Tesuque Formation. Recent work in the Española Basin suggests that "lithosomes" of the Santa Fe Group grade laterally and interfinger, as fault displacements episodically dropped the western margin of the basin. However, the downdropping western margin of the basin, which is beneath the LANL site, may also have been the locus of past flow for major drainages. At this time it is uncertain whether the lithologic variations in these older sediments beneath the site reflect interfingered facies of similar age or unconformable, younger channel deposits in paleocanyons cut into the older Santa Fe Group sands. Resolution of this uncertainty could confirm or rule out the existence of long-distance, high-permeability pathways in the regional aquifer.

2.4.4.5 Spatial Variation in Permeability within Sedimentary Rocks

With the exception of the relatively uniform sandy sub-unit of the Santa Fe Group, variability within hydrostratigraphic units tends to be much larger than variability between hydrostratigraphic units. To understand intra-unit variability, using limited data the possible role of texture (Table 2-5) and alteration (Figure 2-28) have been examined and no consistent relationships were found. There does not appear to be a method to deterministically interpolate the spatial variation in permeability within these sedimentary rocks, given the available data. It is possible that a larger dataset and better information about sedimentary facies (if cores were available, for example) would allow a better understanding of the mechanisms controlling hydraulic conductivity. Even so, local variation may be sufficiently great that accurately

interpolating point data (tests at wells) within a deterministic 3-D framework model from known point estimates may not be feasible.

For the purposes of modeling flow and transport through sedimentary rocks in the saturated zone, it may be more appropriate to use a probabilistic approach based on the statistical properties of the hydraulic conductivity dataset rather than a deterministic approach based on defined geometries of hydrostratigraphic units (Section 4.2.10). Another promising method may be to use head data directly to infer heterogeneities in the aquifer (Doherty et al., 1994).

Although the data suggest there are no large differences in permeability between the volcanic and sedimentary rocks, differences in porosity and storage characteristics are likely to be large. For this reason, it is important to delineate the extent of the volcanic rocks in a 3-D framework model of the site for the purposes of flow and transport modeling.

Available porosity data are very limited; more data could be derived from existing borehole geophysical logs and perhaps a geostatistical model of porosity could be built from those logs.

2.4.4.6 Influence of Structure on Groundwater Flow

The influence of structures on groundwater flow is uncertain, but the evidence suggests that structure plays a role in groundwater flow beneath the Pajarito Plateau. First, the large head gradients across the Pajarito fault zone indicate that the faults exert control on flow. Associated modeling results described in Section 4.2.10 suggest that the Pajarito fault zone and north-south trending faults in the Santa Fe Group may act as flow barriers at large scales. Zones of high permeability in the center portion of the plateau (Figure 2-26), which cross hydrostratigraphic boundaries, suggest that perhaps large-scale features such as faults play an important role here.

Further interdisciplinary work combining geophysics, geochemistry, hydrology, and geology investigations would be required to better understand the processes controlling variability in aquifer properties at this site. Given the large heterogeneities in flow and transport properties and the complexities of the hydrogeologic formations, it is unlikely that transport models can ever be based purely on a deterministic hydrogeologic framework. Rather, models should be based on a blend of deterministic (e.g., 3-D hydrogeologic framework models) and geostatistical approaches.

2.5 Alluvial Groundwater Conceptual Model

The alluvial groundwater conceptual model is based on data collected during investigations of alluvial groundwater systems at LANL that have been conducted to meet various objectives not specific to the Hydrogeologic Workplan (Appendix 1-A). Most of the early investigations were driven by alluvial groundwater contamination concerns in canyons with persistent alluvial saturation along significant segments of the canyon, and most of the early investigations were conducted in Mortandad Canyon. Examples of these studies include those conducted by Purtymun (1974), Purtymun et al. (1983), and Stoker et al. (1992). Many of these investigations were conducted in collaboration with the United States Geological Survey. Additional investigations conducted in the mid-1990s measured alluvial aquifer properties (Koening and Guevara, 1992) and calculated bulk groundwater flow velocity (Gallaher, 1995). Purtymun

(1995) contains a significant body of additional information and references pertaining to alluvial groundwater investigations conducted at the Laboratory up to the mid-1990s.

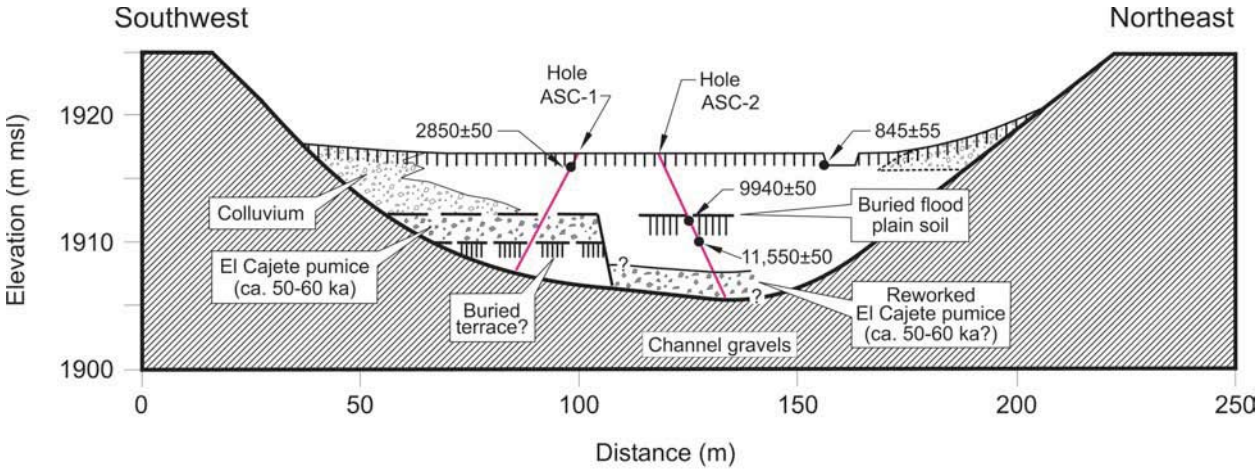
2.5.1 Physical Setting

Average annual precipitation across the Pajarito Plateau ranges from over 0.5 m along the western boundary near the Jemez Mountains to less than 0.36 m to the east at the Rio Grande (Bowen, 1990). Most precipitation occurs either as winter/spring snow or as summer "monsoonal" rains. As a result, most infiltration occurs episodically during spring snowmelts or during the intense summer thunderstorm season.

Surface-water flow in the canyons is generally ephemeral or intermittent, although a few canyons have short stretches with perennial surface flow. Anthropogenic discharges from water treatment outfalls can be a significant source of water in some canyons. Infiltration of these surface sources forms near-surface perched alluvial groundwater systems in many of the canyons (Stone et al., 2001). These alluvial groundwaters are not sufficiently extensive for domestic use. Nevertheless, these waters are an important component of the subsurface hydrologic system. In addition, laboratory contaminants introduced into the canyons can affect shallow groundwaters. Therefore, alluvial groundwaters provide pathways for contamination to migrate to significant lateral distances and potentially to greater depths.

The deposits that comprise alluvial groundwater aquifers are confined to the bottoms of canyons and are composed of axial fluvial deposits interbedded with deposits of alluvial fans, colluvium, and rock fall from adjacent mesa slopes. For watersheds that head on the Pajarito Plateau (e.g., Mortandad and Sandia Canyons), the source of sediment is primarily Bandelier Tuff and, to a much lesser extent, other formations such as the Cerro Toledo interval. Tschicoma dacite and Bandelier Tuff are primary sources of sediment for watersheds that head in the Sierra de los Valles. Canyons that have Bandelier Tuff as the primary source of sediment tend to have predominantly sand-sized alluvial fill with some interbedded coarser-grained side-slope deposits, including colluvium, whereas canyons that head in the Sierra de los Valles have alluvial fill that contains a wide range of grain sizes including dacitic boulders and gravels. Available data indicate that the thickness of alluvium and colluvium in the canyons ranges from a few feet up to approximately 100 feet.

2.5.2 Hydrology



The presence and extent of saturation within the canyons is dependent on a number of variables including source(s) of water, volume and persistence of water sources, the magnitude and location of infiltration of groundwater from the alluvial system to underlying bedrock units (i.e., loss to underlying vadose zone), and evapotranspiration.

These controls on variability of saturation are difficult to quantify, but are based largely on observations made during drilling for installation of alluvial monitoring wells and piezometers in several canyons, including, Los Alamos and Mortandad Canyons, and Cañon de Valle. Adjacent boreholes commonly show different saturated conditions and sometimes a borehole with substantial saturation will be adjacent to one or more boreholes with no or minimal saturation.

This phenomenon is likely related to juxtaposition of facies with highly variable hydrologic properties, such as porosity, permeability, or hydrologic conductivity (Figure 2-30; Reneau and McDonald, 1996).

2.5.2.1 Alluvial Recharge

Recharge to alluvial groundwater systems on the Pajarito Plateau occurs via infiltration from three primary sources: storm-water runoff, anthropogenic effluents, and snowmelt. Each of these recharge sources produces a characteristic groundwater response. The conceptual model for alluvial system recharge on the Pajarito Plateau is based on continuous stream flow, precipitation, and water-level data collected within the Los Alamos and Pueblo Canyon watersheds (including DP Canyon). Three example plots (Figures 2-31, 2-32, and 2-33) show the relations of precipitation, stream flow, and groundwater hydrographs for several representative alluvial monitoring wells in Los Alamos and Pueblo Canyons. The precipitation data shown in the plots are values of average daily precipitation estimated using Theissen weighted averages of precipitation measured within and near the watershed (Dunne and Leopold, 1978). This approach is described in greater detail in LANL (2004) and in Reneau and Kuyumjian (2005). These examples are believed to be representative of canyons across the plateau.

Note: The numbers shown at the dots are radiocarbon dates in years before the present.
Source: Reneau and McDonald (1996).

Figure 2-30. Schematic cross section of complex stratigraphy within the alluvial package in Ancho Canyon.

Examples of recharge via infiltration of storm water are shown in Figure 2-31. The water-level record for monitoring well LAO-0.3 in Los Alamos Canyon is plotted against precipitation data and the stream flow record at gaging stations E025, E030, and E042. The water-level data show generally rapid rises in response to summer and fall precipitation events and associated storm water runoff. Good examples are the large precipitation events in mid-August 2001 and late June 2002. These water-level rises occur instantaneously and generally correlate well with the stream flow record, indicating infiltration into the streambed during floods. The duration of the recessional limb varies between events. Several small but distinct increases in the water-level recorded during late spring and summer months are not related to precipitation events, but rather are related to draining of the Los Alamos Reservoir for dredging and maintenance following the Cerro Grande fire. Storm-water runoff can be generated from precipitation in upland portions of watersheds, directly onto the plateau, or on impervious surfaces in developed areas within the Laboratory or in the Los Alamos townsite.

Effluent-supported recharge results in more sustained and consistent water levels, as shown in Figure 2-32. Groundwater levels observed in monitoring well PAO-4 are dominated by infiltration of effluent discharged from the Bayo wastewater treatment plant (WWTP) to the stream channel in Pueblo Canyon (Figure 2-2). The variation in water-level elevations down canyon of the WWTP is controlled primarily by seasonal rerouting of effluent for "downstream" uses such as watering at the Los Alamos County golf course. Other examples of canyon reaches with similar effluent-supported recharge include effluent/upper Mortandad Canyon (TA-50 outfall) and upper Sandia Canyon (power-plant outfall). These sources represent relatively consistent sources of recharge to alluvial groundwater creating stable alluvial groundwater levels. During dry periods in drier canyons that have little natural runoff, anthropogenic sources provide the majority of groundwater recharge.

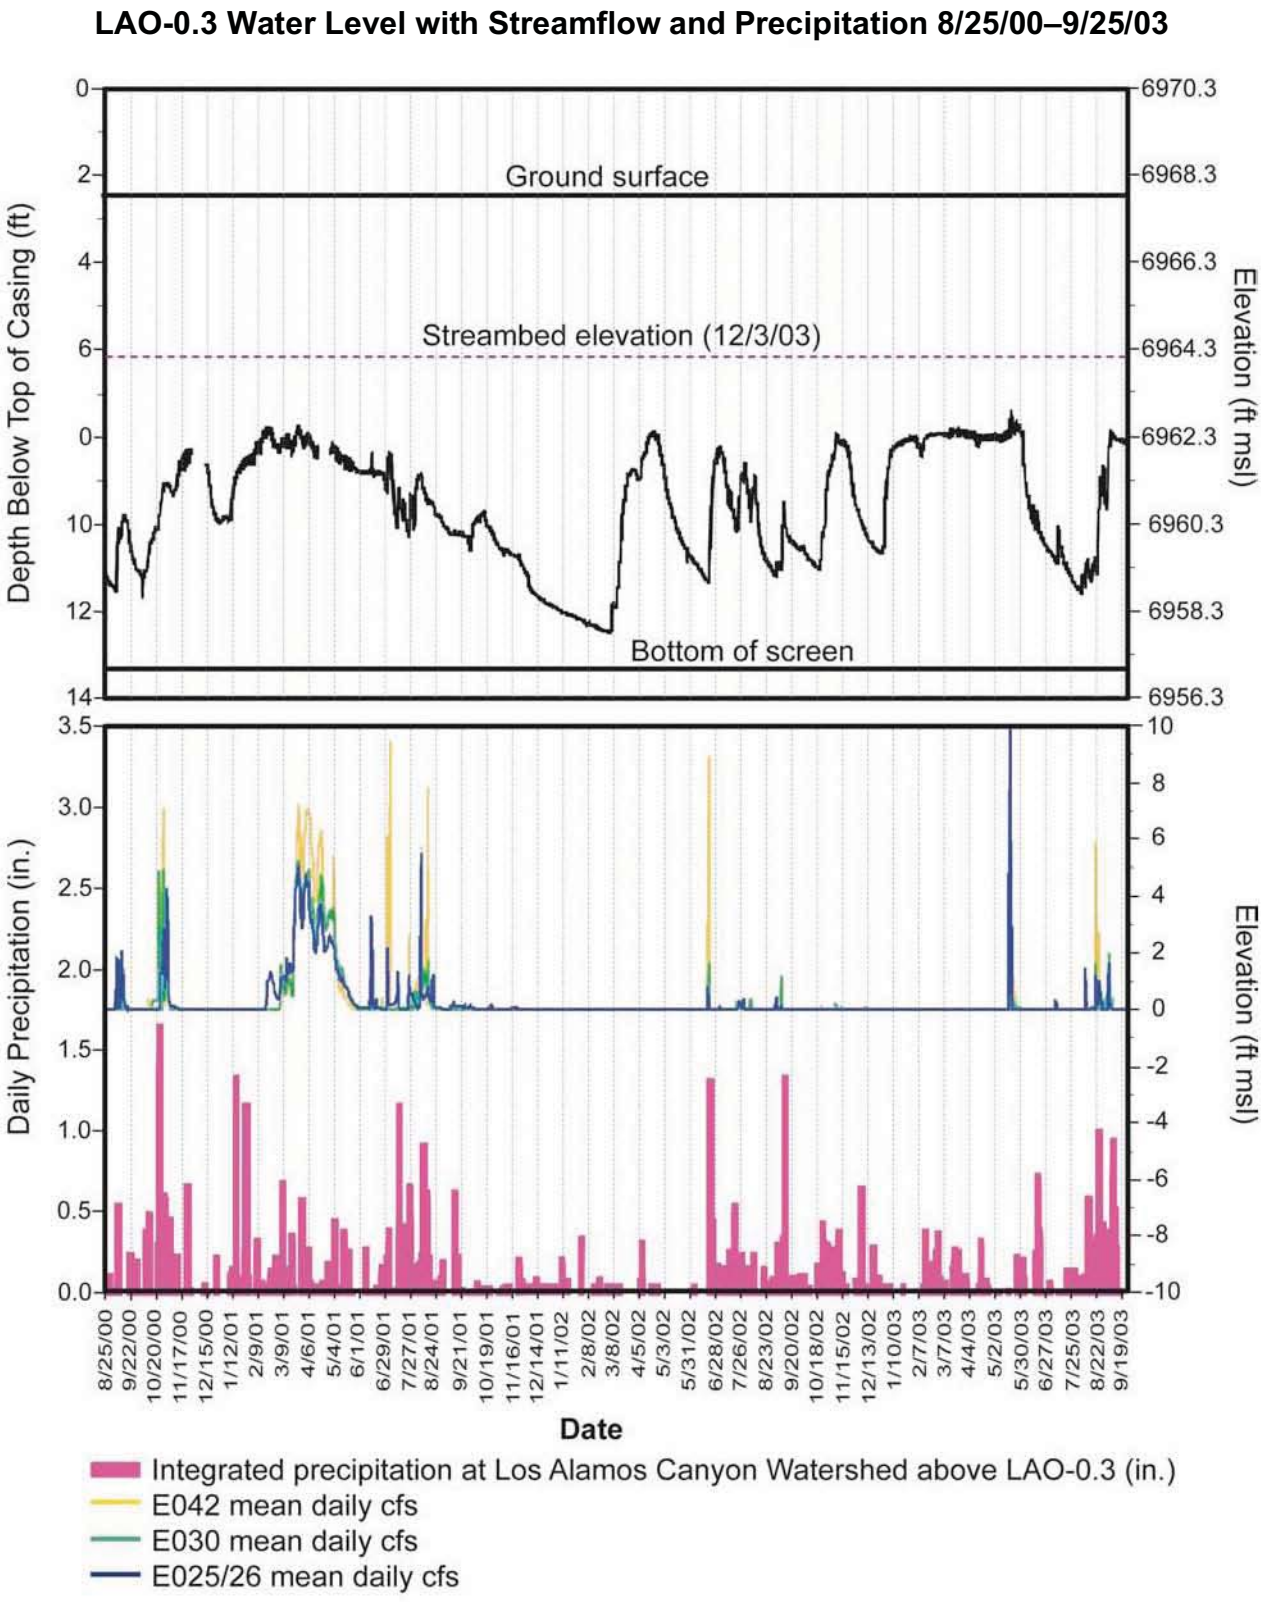


Figure 2-31. LAO-0.3 water level with streamflow and precipitation.

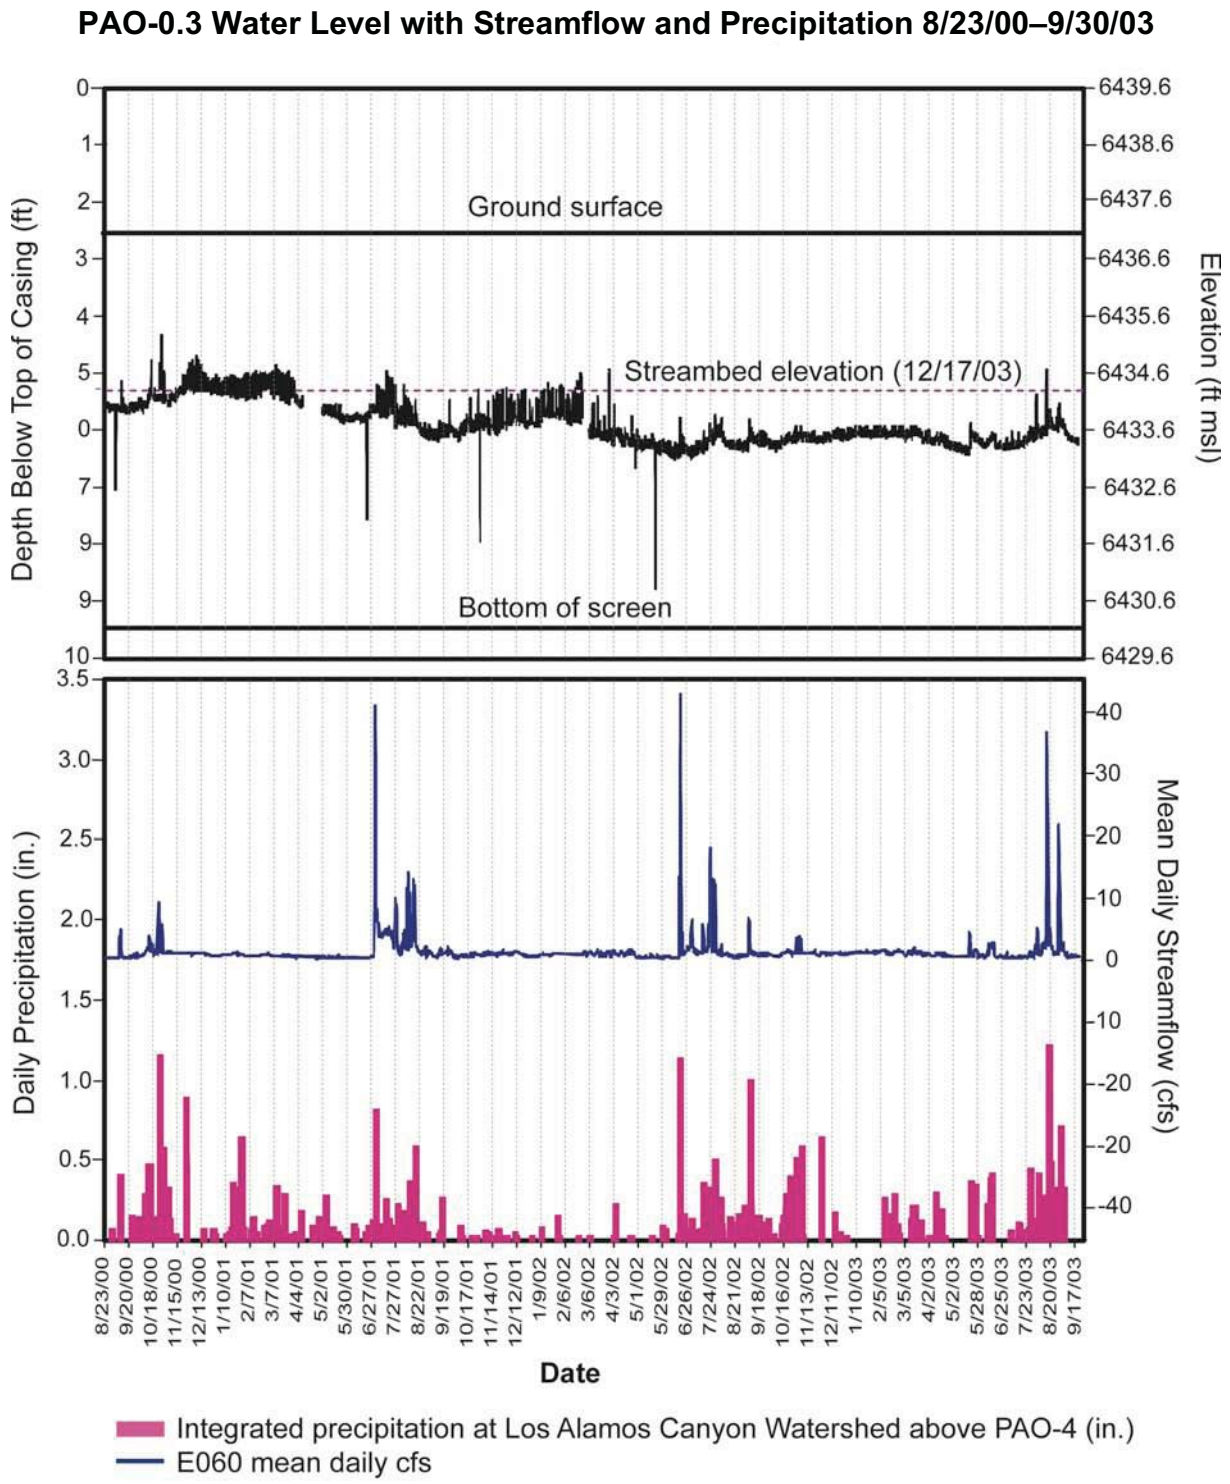

Figure 2-32. PAO-4 water level with streamflow and precipitation.

Recharge also occurs in response to winter/spring snowmelt. Figure 2-31 shows rising alluvial groundwater levels during the late winter to early spring of each of the years represented on the plot. All three winter/spring periods show alluvial-groundwater-level responses prior to initiation of sustained streamflow at even the most up-canyon gaging station, E025. The winter and spring

of 2000–2001 alluvial-groundwater-level shows a substantial response to snowmelt runoff from an appreciable winter snowpack. The alluvial-groundwater-level response occurs over one month prior to initiation of stream flow at E025. The conceptual model for this type of response is that recharge within the alluvium is associated with early-season snowmelt that infiltrates into alluvium in the upper canyon and creates an underflow recharge front that advances down canyon. Once the aquifer saturation has reached capacity (i.e., the elevation of the adjacent stream channel), stream flow is initiated, suggesting that stream flow during these periods represents discharge from the aquifer to the channel.

Figure 2-33 shows groundwater-level data from four alluvial groundwater monitoring wells in Los Alamos Canyon. Initiation of the alluvial-groundwater-level rise in the winter/spring of 2001 at each well occurs prior to the onset of sustained surface water flow. This suggests that the persistent baseflow conditions associated with snowmelt infiltration may actually be sustained largely from discharge of groundwater to the channel. Long-duration snowmelt runoff is most significant in watersheds with upland drainage basin areas, although watersheds that drain developed areas with pavement and storm-drain systems can provide short-duration, pulsed snowmelt runoff associated with melt from individual events.

The down-canyon extent of alluvial groundwater saturation varies significantly from year to year and seasonally. During dry years, and especially during years with limited spring snowmelt runoff, saturation may not extend far from the upland sources of snowmelt recharge.

Gray (1997; 2000) and LANL (2004) investigated alluvial groundwater in Los Alamos Canyon, creating a numerical model that calculated infiltration of alluvial groundwater to the underlying vadose zone. Results indicate that the alluvial groundwater infiltrates into the underlying vadose zone at variable rates along the length of the canyon with a higher rate of loss estimated for a portion of the canyon coincident with the projected trace of the Guaje Mountain fault (mapped to the north but not evident in the walls of Los Alamos Canyon). Nested piezometer data from Los Alamos Canyon (LANL 2004) corroborate modeling results indicating greater infiltration rates in the vicinity of the projected Guaje Mountain fault. The variability in infiltration rates is interpreted to be caused by either loss into permeable units underlying the alluvium or loss within zones of relatively greater fracture size or density.

In addition to the watershed-scale investigation of alluvial groundwater responses to various recharge sources, site-specific alluvial groundwater investigations have been conducted in DP Canyon and in Cañon de Valle. A potassium bromide tracer study was conducted in DP Canyon in 2003 to investigate alluvial groundwater travel times, surface water/groundwater exchange, hydrologic linkage from reach DP-2 to DP Spring, and to measure vertical hydraulic gradients and seepage velocity into the underlying Bandelier Tuff. The primary conclusions regarding alluvial recharge from this study were that surface water/groundwater exchange is an important recharge mechanism and that groundwater flow is transient, primarily controlled by episodic recharge from townsite runoff. For a detailed description of these findings, see LANL (2004) and LANL (2003a).

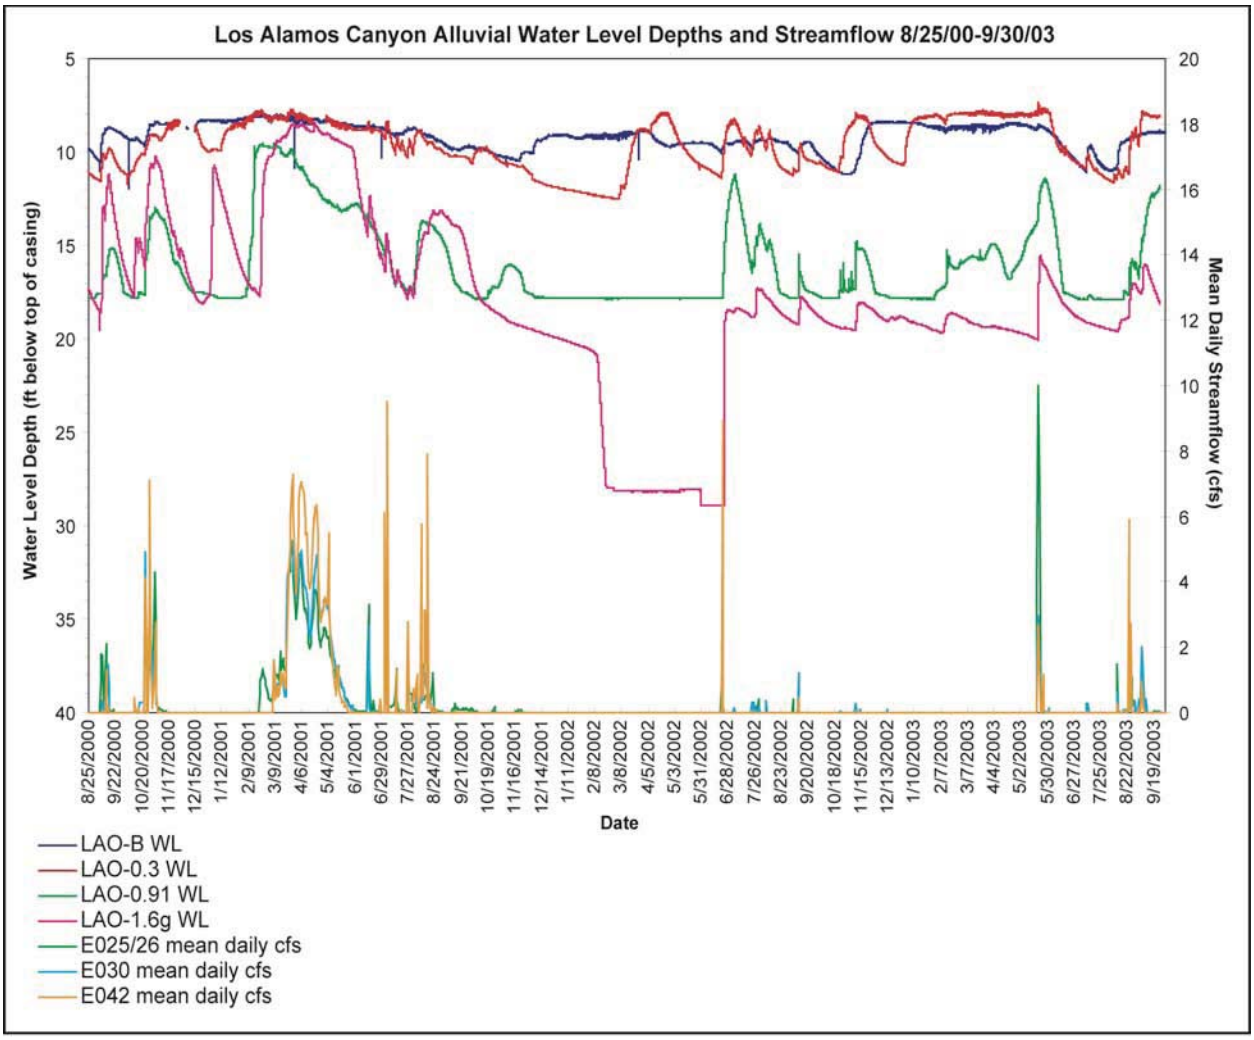

Figure 2-33. Los Alamos Canyon alluvial water level depths and stream flows.

To quantify infiltration, Kwicklis et al. (2005) developed a map of average annual "net infiltration" in the Los Alamos area, based on physical features such as elevation, vegetation, surface geology and stream flow (Figure 2-34). They define net infiltration as that water remaining after accounting for evapotranspiration in the shallow subsurface (i.e., the root zone). They estimate the highest net infiltration rates in canyons, especially those that head in the mountains, with magnitudes of up to a few hundred millimeters per year caused by channelized runoff. In contrast, much lower net infiltration rates occur across mesas and in the smaller canyons that head on the plateau (see Section 4.1 for a site-wide numerical model employing these concepts).

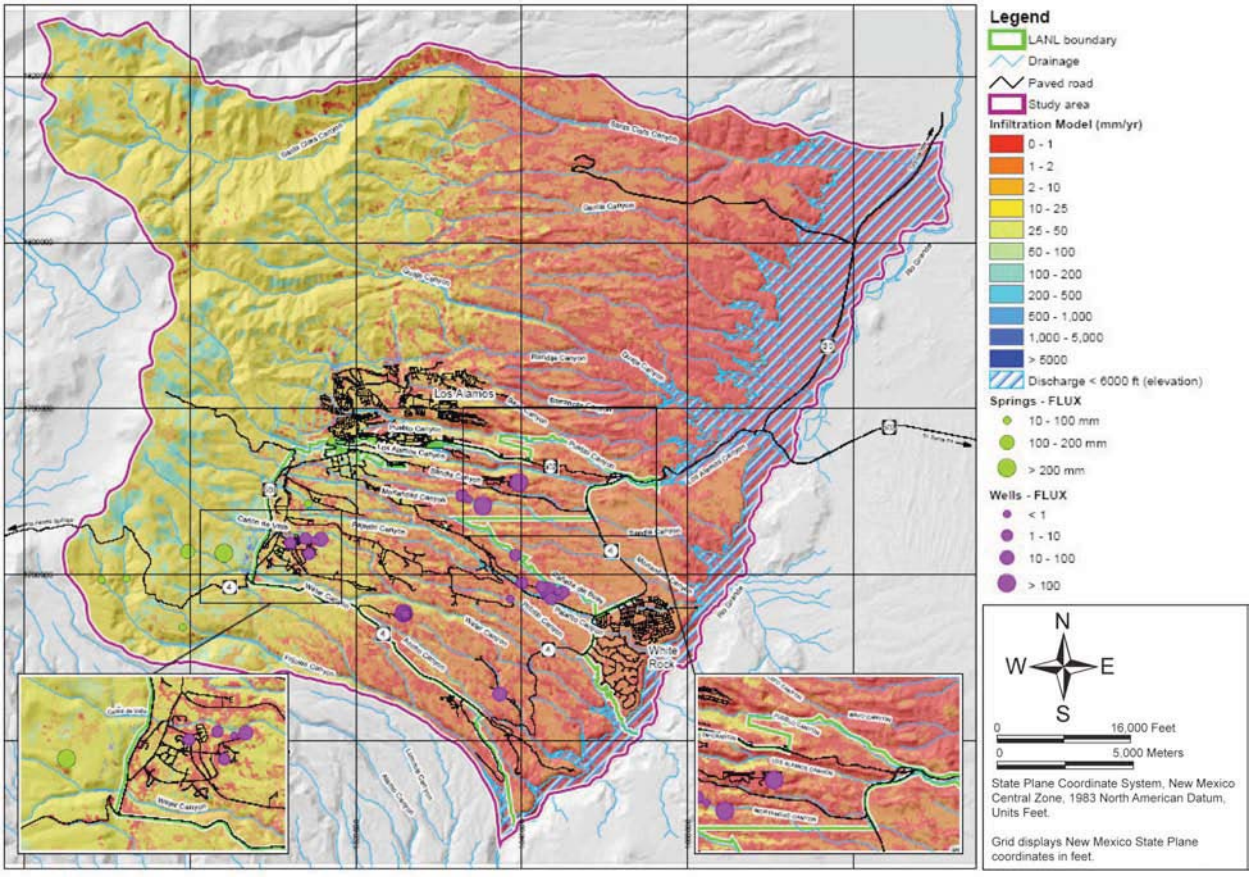

Figure 2-34. Estimated infiltration on the Pajarito Plateau (reproduced from Kwicklis et al., 2005).

2.5.2.2 Alluvial Aquifer Properties

Observations of alluvial groundwater were initially focused on understanding the distribution of contaminants. Purtymun (1974) performed one of the first quantitative investigations where groundwater velocities were calculated from a tritium release in Mortandad Canyon. The release from the TA-50 outfall was a planned event staged to discharge wastewater containing elevated tritium. Groundwater velocities calculated from travel time of the tritium centroid showed values ranging from 20 meters/day in the upper canyon, where alluvium is thin and the alluvial aquifer volume is small, to approximately 2 meters/day in the lower canyon where the canyon widens and alluvium thickens to approximately 30 meters (Table 2-7). These observations indicate that alluvial groundwater flow can be highly variable along the length of a canyon. Other factors influencing system-scale groundwater velocity include aquifer sediment textures, stratigraphic complexity, and hydraulic gradient.

Gallaher (1995) calculated Darcy velocity (Table 2-7) from mean saturated hydraulic conductivities (Table 2-8) and water table gradients in Los Alamos Canyon. Using the results from slug tests conducted by Koening and Guevara (1992), Gallaher estimated the rate of groundwater movement in alluvium at 0.75 meters/day. Additional saturated conductivity values for Los Alamos and Mortandad Canyons are presented in Table 2-8. Slightly lower hydraulic

conductivities in middle Mortandad Canyon may be due to an overall fining of the alluvial material in that portion of the canyon.

Gray (1997, 2000) measured aquifer parameters, calculated a hydrologic budget and performed numerical modeling of groundwater flow in Los Alamos Canyon. Hydraulic conductivity measurements from these studies are included in Table 2-9.

2.5.2.3 Cerro Grande Fire Effects

The May 2000 Cerro Grande fire produced significant hydrologic changes in the watersheds west of the Laboratory (BAER 2000). Loss of vegetation and forest litter, development of ash covers, and extreme hydrophobic soil conditions, primarily in the upland portions of watersheds, greatly reduced the capacity for infiltration and storage of precipitation. Rapid surface-water runoff in the first two summer monsoon seasons following the fire contained high ash content with a complex mixture of inorganic and organic compounds. Calcium, magnesium, silica, potassium, sodium, and carbonate were among the constituents concentrated in the ash (Longmire et al., 2002).

A detailed water-level and water-quality record was obtained from Los Alamos and Pueblo Canyons using dedicated multiparameter pressure transducers installed in a series of alluvial monitoring wells. Hydrologic system effects were manifested as rapid water-level response to numerous post-fire floods and possibly also earlier-than-typical onset of a snowmelt runoff response. Reduced or eliminated forest canopy is thought to have allowed winter snow to melt shortly after individual precipitation events and early in the spring. There were stormwater related excursions in water-quality parameters, including increases in pH in the alluvial groundwater and elevated concentrations of several constituents in alluvial groundwater due to infiltration of ash-rich storm water. A detailed discussion is presented in Chapter 7 and Appendix B of the Los Alamos and Pueblo Canyons Investigation Report (LANL, 2004). It is not known how long such perturbations will persist, although the effects of the fire are expected to progressively decrease over time as the upper watershed recovers.

2.6 Vadose Zone Conceptual Model

The vadose zone is the section of soil and rock material between the alluvial groundwater or the ground surface (where alluvial groundwater is not present) and the regional aquifer water table. Beneath the Pajarito Plateau, the thickness of the vadose zone ranges from about 600 feet to over 1,200 feet. Intermediate-depth perched groundwaters are present within the vadose zone. Specific intermediate perched zones that occur beneath major canyons and in the western portion of the Laboratory are described in Section 2.7.

Table 2-7.
Groundwater Velocities in Alluvial Aquifers on the Pajarito Plateau

Measure Locations	Source	Distance between Measurement Points (m)	GW Velocity (m/d)	Test Type
Upper Los Alamos Canyon	A	Approximately 7000	0.75	Calculated from (mean K_s[A]), average gradient of stream channel (0.027), and an estimated porosity of 0.3.
Mortandad Canyon				
MCO-5 to MCO-6	B	393	^{3}H 16 Cl 25	Tritium (^{3}H) and chloride (Cl) TA-50 discharge tracer test
MCO-6 to MCO-7	B	320	^{3}H 4.2 Cl 5.1	Tritium (^{3}H) and chloride (Cl) TA-50 discharge tracer test
MCO-7 to MCO-7.5	B	290	^{3}H 4.4 Cl 5.6	Tritium (^{3}H) and chloride (Cl) TA-50 discharge tracer test
MCO-7.5 to MCO-8	B	185	^{3}H 1.7 Cl 2.3	Tritium (^{3}H) and chloride (Cl) TA-50 discharge tracer test

Note: Calculated groundwater velocity using mean saturated hydraulic conductivity from LAO-C, LAO-1, LAO-2, LAO-3, LAO-3A, LAO-4, LAO-4.5A, LAO-4.5C, LAO-5.

2.6.1 Climate and Infiltration

Arid and semi-arid regions often exhibit thick vadose zones. Infiltration is often focused in topographic lows or beneath surface water bodies, rather than being diffuse, as is common in wetter climes (e.g. Sanford, 2002). The average annual potential evapotranspiration (PET) rates far exceed precipitation rates. Under these conditions, infiltration events that propagate beneath the root zone are sporadic and occur only when the short-term infiltration rate exceeds the ET rate, such as during snowmelt or after large rainstorms. Consequently, the rates for deeper infiltration are difficult to quantify through traditional water balance studies because this component of the water-balance can be orders of magnitude smaller than the other components (Devries and Simmers, 2002; Scanlon et al., 2002; Sophocleous, 2002; Sanford, 2002; Flint et al., 2002). These generalities apply to the near-surface hydrology of the Pajarito Plateau, which has a semiarid climate.

The infiltration rate estimates from canyon bottom alluvium and mesa top sites developed by Kwicklis et al. (2005) (Figure 2-34) can be tested for consistency against the estimated infiltration rates inferred from moisture content profiles. In Section 4.1.3.2, a set of numerical models for wells LADP-3 and LADP-4 in Los Alamos Canyon are presented showing that moisture profiles reflect the conceptual model of high infiltration in canyons and low infiltration in mesas. That analysis also shows that the uncertainties associated with such estimates are quite high (in the range of a factor of 3). However, by combining moisture content, tracer or contaminant profiles, and water budget information, a more constrained estimate can be achieved. One of the purposes of the vadose zone numerical models being developed is to provide the additional constraints afforded by the use of multiple, independent data sets (Robinson et al. 2005a).

2.6.2 General Description of Conceptual Models

Conceptual models for vadose zone flow and transport on the Pajarito Plateau are based on observations from a variety of data sources, including both mesa-top and canyon sites under both natural conditions and disturbed conditions resulting from Laboratory operations. The key conceptual-model elements describe percolation of water through both fractured and relatively unfractured volcanic tuffs, buried sedimentary formations, and basalts. The types of data incorporated into the development of the conceptual models include water content and pore-water chemical compositions from borehole samples for naturally occurring tracers, introduced tracers, and Laboratory contaminants.

The conceptual models differentiate the rate of percolation by their location and surface hydrologic setting, including wet and dry canyons, and wet, dry, and disturbed mesas. Perched water is often found beneath wetter canyons, either associated with near-surface alluvial systems or at intermediate depths, along low-permeability interfaces such as buried soils and unfractured or clay-filled horizons of basalt flows. Alluvial groundwater is discussed in Section 2.4, while perched water is addressed in Section 2.6. The generalized view of the role of wet and dry canyons on vadose zone flow and transport is quantified in the numerical model section of this report (Section 4).

2.6.2.1 Mesas

Dry finger mesas constitute most of the mesa area on the plateau. The hydrologic conditions on the surface and within these dry mesas lead to slow unsaturated flow and transport. The mesas shed precipitation as surface runoff to the surrounding canyons such that most deep infiltration occurs episodically following snowmelt (Section 2.4.2.1). Much of the water that does enter the soil zone is lost through evapotranspiration (ET). As a result, annual net infiltration rates for dry mesas are less than ten mm/yr and are more often estimated to be on the order of one mm/yr or less (Kwicklis et al., 2005). Since the dry mesas are generally comprised of nonwelded to moderately welded tuffs with low water content, flow is likely to be matrix dominated. Wetter mesas, supporting ponderosa forest above densely welded and fractured tuff in the western portion of the plateau, may provide fracture flow to a few meters to tens of meters depth but evidence of fracture infiltration usually diminishes at the depth of the first nonwelded horizon. For most of the LANL site, travel times for contaminants migrating through mesas to the regional aquifer are expected to be several hundred to thousands of years (Newman, 1996; Newman et al., 1997b; Birdsell et al., 2000; and Section 4.1.1 of this report).

The topographic relief of these steep-sided mesas influences their internal hydrologic conditions as well. High solar radiation, strong winds, and fluctuations in barometric pressure cause temperature and pressure gradients between the surface of the mesa and its interior. These gradients enhance air circulation through the mesas, which is thought to enhance deep evaporation (Neeper 2002; Neeper and Gilkeson, 1996; Newman, 1996; and Newman et al., 1997b). This additional drying in the mesa-top units further slows downward water flow and transport of dissolved species. However, these same conditions enhance vapor transport of volatile species (Stauffer et al., 2005).

Anthropogenic discharges and surface disturbances due to laboratory operations can drive infiltration rates higher in usually dry mesas. In some cases, multiple disturbances of mesa sites through liquid waste disposal, asphalt covers, and/or devegetation have caused mesa infiltration rates to temporarily increase to near wet canyon levels (representative values are given in Section 4.1). Even with elevated infiltration, at most sites flow remains matrix dominated. Fracture flow has occurred in a few instances beneath long-term liquid disposal sites with ponded conditions. However, fracture flow ceases once liquid disposals stop. Infiltration rates are expected to return to low, near-background levels when the surface and vegetation return to natural conditions.

An exception to the general concepts just discussed occurs for mesas along the mountain front of the plateau. Due to their higher elevation, these mesas receive higher precipitation and higher infiltration than the drier mesas in the central and eastern portions of the plateau (Birdsell et al., 2005). Mountain-front areas also have units of the Tshirege Member that are more strongly welded, yielding rocks with more fracturing and lower matrix permeabilities. Under these conditions, infiltrating water travels laterally through fractures and other fast pathways, often issuing at springs that feed the canyons in this area. These near-surface processes can be thought of as sources for deeper vadose zone transport from canyon bottoms, although the possibility of deeper vertical migration from the mesa source without first entering the canyon is also possible.

2.6.2.2 Canyons

This section summarizes the hydrologic conditions present in canyons characterized as either wet or dry. Several features characterize naturally wet canyons on the Pajarito Plateau. Their headwaters are in the mountains, they have large catchment areas (13 to 26 km^2), surface flow occurs frequently, and alluvial groundwater systems exist in the canyon floors. In some cases, anthropogenic sources can elevate flows sufficiently in smaller dry canyons that head on the plateau so that they act as wet canyons. In addition, springs issuing from the sides of mesas are a water source in the mountain front canyons; these springs are a characteristic of wet canyons in the western portion of the plateau. Often, deeper, intermediate perched zones are associated with wet canyons. The geometry of wet canyons promotes hydrologic conditions that yield relatively fast, unsaturated flow and transport.

Wet canyons such as Los Alamos Canyon receive large runoff volumes, either through channeling of precipitation or through wastewater discharges. This runoff, in turn, creates surface-water flow along canyon bottoms, which subsequently infiltrates to form near-surface, alluvial water bodies (Section 2.4.2.1). Lateral flow and transport through surface water and in the alluvial systems are rapid with respect to other subsurface hydrologic processes on the plateau. Rates of lateral transport are even higher during surface flow events, which occur more frequently in the larger wet watersheds than in other areas of the plateau. Sorbing species transport slowly in alluvial waters and more commonly migrate down the canyon floor by sediment transport (LANL, 2004; Lopes and Dionne, 1998; Solomons and Forstner, 1984; and Watters et al., 1983).

It has been suggested that trace quantities of strongly sorbing contaminants can travel via colloid-facilitated transport in the alluvial groundwater (Penrose et al. 1990), although this interpretation of the data from Mortandad Canyon has been called into question (Marty et al., 1997). Since some of the wet canyons that cross Laboratory land have received liquid-waste discharges from outfalls, the alluvial systems act as line sources for both water and contaminants to the deeper vadose zone beneath such canyons (Birdsell et al., 2005). The term “line source” denotes that infiltration is likely at any location along the region defined by the alluvial groundwater; there are probably preferential zones of enhanced infiltration at certain locations that will yield larger than average travel velocities through the deeper vadose zone. The net percolation rates beneath the alluvial systems of wet canyons to the underlying unsaturated zone are expected to be among the highest across the plateau, approaching meters per year (100 - 1000 mm/yr) (Kwicklis et al., 2005).

In addition, the vadose-zone thickness decreases with increasing distance down canyon, due to thinning of the Bandelier Tuff (Section 2.2.9). This is especially true for the deep wet canyons because their canyon bottom elevations are 45 to 60 m lower than smaller canyon systems on the plateau. Contaminants transported down canyon via surface flow or through the alluvial groundwater system often percolate through a geologic column consisting primarily of basalt and fanglomerate with little or no overlying tuff. Downward percolation is believed to be more rapid in the basalt than through moderately welded tuff (Section 2.2.8). Thus, these wet canyons have thinner vadose zones and a smaller portion of the flow path with matrix-dominated flow.

These stratigraphic factors, compounded by the relatively high deep-percolation rate in wet canyons, likely yield the fastest vadose-zone travel times for contaminants from the land surface of the plateau to the regional aquifer. Transport to the regional aquifer beneath wet canyons is predicted to be on the order of decades to hundreds of years (see Section 4.1 for details).

In contrast to wet canyons, dry canyons such as Potrillo Canyon and Cañada del Buey head on the plateau, have smaller catchment areas (less than 13 square km), experience infrequent surface flows, and have limited or no saturated alluvial systems in their floors. If anthropogenic sources are present, they are small volume sources. These hydrologic factors yield little lateral near-surface contaminant migration and slower unsaturated flow and transport from the surface to the regional aquifer. For example, because surface and alluvial waters are less common, contaminants remain close to their original source locations. Pathways through the vadose zone tend to be longer in the shallow dry canyons that have thicker sections of nonwelded to moderately welded tuff than the deeper-cut wet canyons. Net infiltration beneath dry canyons is much slower, with rates generally believed to be less than tens of millimeters per year and commonly on the order of 1 mm/yr. Finally, transport times to the aquifer beneath dry canyons are expected to be much longer than travel times from the bottom of wet canyons.

2.6.3 Vadose Zone Flow and Transport Mechanisms

Given the description in the previous section of surface and near-surface hydrologic conditions, the next step is to consider the flow and transport mechanisms for water that infiltrates into the subsurface. Most of the plateau is covered with nonwelded to moderately welded Tshirege and Otowi Member ash-flow tuffs (Section 2.2.9). Unsaturated flow and transport through these nonwelded to moderately welded tuffs is thought to occur predominantly through the porous matrix. These units are quite porous, with typical porosities of 40 to 50%, moderate saturated hydraulic conductivities (e.g., 10^{-4} cm/sec), and water contents that are generally far below saturated conditions (2 to 25%) (Abrahams et al., 1961; Rogers et al., 1996a; Birdsell et al., 2000; Springer, 2005).

Although the tuff units are often fractured, flow is expected to be matrix dominated unless conditions approach full saturation due to the presence of a high-flow-rate, constant water source (Soll and Birdsell, 1998), such as beneath liquid-waste disposal pits or outfalls. This result is a consequence of the difference in capillary pressure behavior in a porous matrix versus within a fracture. Even if water is injected into a fracture, capillary forces tend to pull water into the rock matrix over a relatively short flow distance. This concept has been established for a wide variety of fracture and matrix hydrologic properties (e.g., Nitao and Buscheck, 1991; Robinson and Bussod, 2000; Soll and Birdsell, 1998; Robinson et al., 2005a, 2005b).

Field observations and analyses support the matrix-flow hypothesis. Robinson et al. (2005b) modeled a vadose-zone, wellbore injection test that was performed in the Tshirege Member of the Bandelier Tuff (Section 2.2.9.3) and reported by Purtymun et al. (1989). Their analysis examined different numerical representations for the fractured porous medium, including a discrete fracture model, a matrix-dominated continuum model, and a dual-permeability representation. Figure 2-35 shows the field-measured moisture profiles at different times during the injection. Water diffused laterally downward, and upward in a relatively uniform fashion,

rather than percolating rapidly through a fracture network. The agreement between the matrix-dominated model and the observations was acceptable, both qualitatively and quantitatively (Robinson et al. 2005b). They estimated an equivalent infiltration rate during the injection phase of about 2.7×10^4 mm/yr, which is greater than any estimates of infiltration across the plateau. They concluded that if matrix-dominated flow is observed at the high effective infiltration rate of this injection test, then it is even more likely to be the case under natural conditions on the plateau.

As discussed in Section 2.6.2.1, this general picture that applies in the eastern portion of the Pajarito Plateau must be modified for areas near the mountain front on the western edge, where some of the Tshirege units of the Bandelier Tuff have densely welded intervals as a result of being closer to the volcanic source (Section 2.2.9.3). These more welded units are less porous, with porosities ranging from 17 to 40%, and have low saturated hydraulic conductivities (e.g., 10^{-6} to 10^{-9} cm/sec) (LANL, 2003b). They are also more fractured and can support fracture flow and transport when sufficient water is present. A bromide tracer test and high explosives contaminant distributions suggest that both fracture and matrix-dominated flow can occur near the mountain front depending on the degree of welding (or matrix conductivity) of the tuff (LANL, 1998b; LANL, 2003b). Therefore, the location and degree of welding of the tuff units affects the degree to which fracture flow will be sustained.

In contrast to the behavior of the Bandelier Tuff units, much of the vadose zone flow through the basalt units is almost certainly fracture dominated (flow-base rubble and scoria may also be highly permeable, but these are stratified components of generally limited vertical extent). Under ponded conditions, rapid flow through fractured basalt has been observed (Stauffer and Stone, 2005). The Laboratory fielded an experiment on the upstream side of a low-head weir located in Los Alamos Canyon (Stone and Newell, 2002). Figure 2-36 is a schematic of the field experimental setup. The objective of the experiment was to monitor flow and bromide tracer transport through fractured basalt under typical unsaturated and periodically ponded conditions using three observation boreholes. Following three ponding events, the bromide tracer advanced quickly downward to a depth of several tens of meters in 10 to 14 days after the first ponding event (Stauffer and Stone, 2005). These observations confirm that fracture flow and transport occurs through basalts under ponded conditions. Model calibration of the bromide transport yields an effective fracture porosity in the range of 10^{-2} to 10^{-3} and saturated hydraulic conductivity in the range of 10^{-2} to 10^{-3} cm/sec (Stauffer and Stone, 2005). In fact, the data and simulations both indicate that the bromide continued to advance through the fractured system even after the all the ponded water had infiltrated.

However, under drier conditions no direct observations have been made of vadose-zone flow and transport in these deeper locations. For this reason, the conceptual model for unsaturated flow and transport through basalts is still evolving.

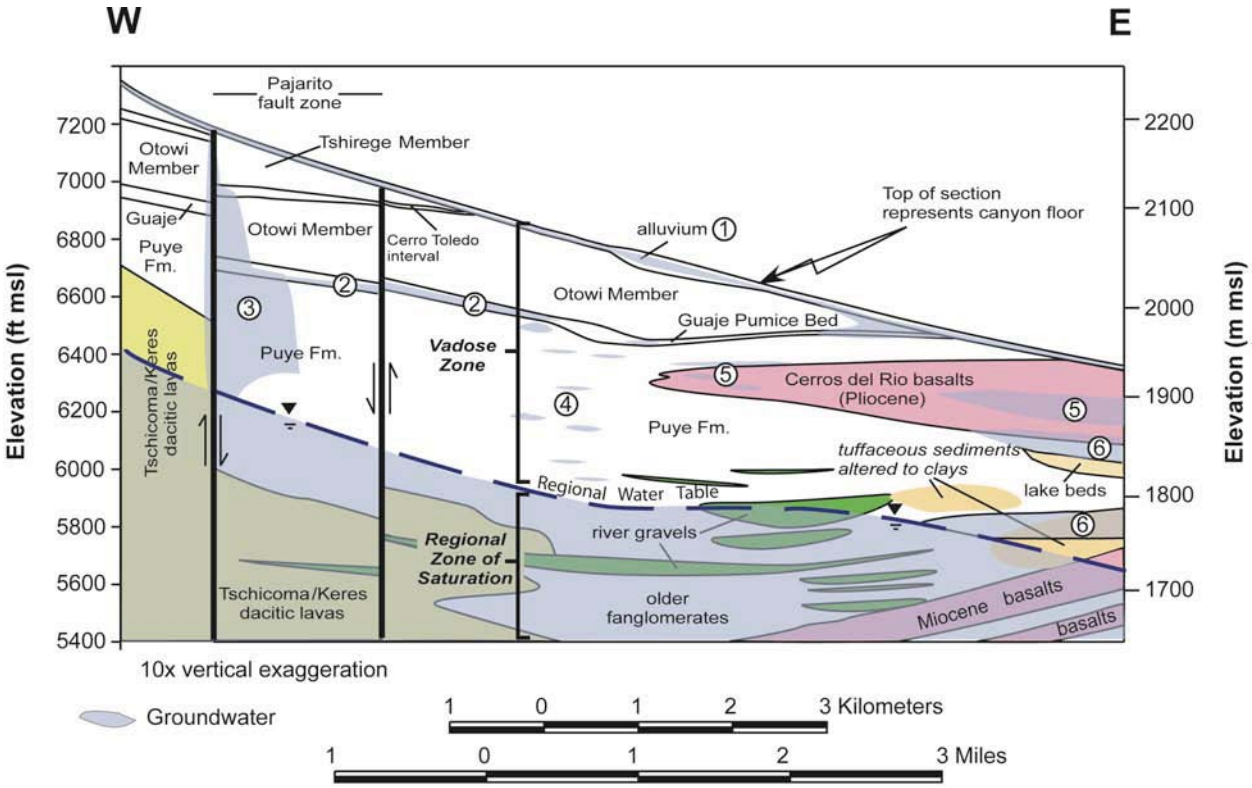
2.6.4 Alternative Hypotheses

Although the basic processes outlined in the preceding sections are supported by the available data and observations and form the best current conceptual model, alternative hypotheses are possible and cannot be completely ruled out by the available information. This section briefly discusses the potential alternative conceptual model of fracture flow. In addition, alternative conceptual models for the mechanisms of flow within perched water zones are described in Section 2.7.

Fracture flow through the Bandelier Tuff is a conceptual model that is often proposed, in contrast to the conceptual model of matrix-dominated flow and transport discussed earlier. Although the available information is consistent with matrix flow, it is possible that in certain situations, fracture flow is important, including the examples related to mountain front processes described earlier. Despite the fact that water input into fractures tends to imbibe into the rock matrix, the observations presented earlier may capture the flow behavior of most, but not all of the water flow. It is possible that preferential flow paths through Bandelier Tuff fractures allow a small portion of the infiltrating fluid to travel to significant depths, even though most water imbibes into the matrix. Alternatively, unstable fingering flow through heterogeneous matrix rock could also lead to preferential downward flow. Regarding the TA-50 water injection test, it is possible that a small amount of fast-moving water could have escaped detection and traveled to greater depths via these mechanisms. The implication of this uncertainty is that small quantities of contamination could potentially be observed at some point in the future at greater depths than

"expected." If this occurs, then we will need to assess whether a relatively small, fast-moving fraction of a released contaminant, combined with a center of mass that travels much more slowly, poses a significant threat to groundwater.



2.7 Perched Water

A common feature of vadose zone flow systems is the presence of perched water. Perching can occur for a number of reasons, including capillary barriers and low-permeability barriers coupled with complex stratigraphic structures in the subsurface (e.g., Bagtzoglou, 2003a, 2003b). Beneath the Pajarito Plateau, perched waters may be important components of subsurface pathways that facilitate movement of contaminated fluids from the ground surface to the water table of the regional aquifer. These perched groundwater bodies are generally too small for use as municipal water supplies. Nonetheless, they are of interest because (1) they represent natural groundwater resources that are protected under State law, (2) their chemical and isotopic characteristics help constrain groundwater transport rates through the vadose zone, (3) their presence may divert, slow, or stop the vertical migration of groundwater through the vadose zone, or they may indicate the presence of a fast subsurface pathway, depending on the characteristics of the perched zone, and (4) they can be used as vadose zone monitoring points that provide early warning of contaminants approaching the regional aquifer.

Characterization of these groundwater bodies is challenging because of the thickness of the vadose zone, the heterogenous nature of bedrock geologic units that serve as host rocks and perching horizons, and the depths of groundwater occurrences. Despite these limitations, substantial new information has been gathered about intermediate perched zones on the plateau. This section summarizes information about the location, depth to water, saturated thickness, and geologic setting of perched water occurrences beneath the Pajarito Plateau. This summary includes data from historical investigations and much new information collected as part of the Hydrogeologic Workplan characterization program.

2.7.1 Perched Water Occurrence

The different modes of groundwater occurrence beneath the Pajarito Plateau are shown conceptually in Figure 2-37. Contaminant distributions in groundwater strongly suggest that groundwater of the plateau alluvial systems is in communication with intermediate perched and regional aquifer groundwater to varying degrees. The focus of this section is the intermediate perched groundwater; a description of the alluvial groundwater is presented in Section 2.5, and the regional aquifer is described in Section 2.8.

1. Canyon-floor alluvial groundwater—most commonly found in large, wet watersheds with significant snow and storm run off or in smaller watersheds that receive liquid effluent from wastewater treatment plants. Saturated thickness and down-canyon extent varies seasonally.
2. Perched ground water is associated with the Guaje Pumice Bed in Los Alamos Canyon. This perched water body has a lateral extent of up to 3.7 mi Guaje Pumice Bed has a high moisture content but is not fully saturated in most other locations.
3. Cañon de Valle area in the southwest part of LANL. This is the largest perched zone identified on the plateau. A deep-sounding surface-based magnetotelluric survey suggest that this perched zone is discontinuous laterally, occurring as vertical pipe-like groundwater bodies. One interpretation of this zone is that it represents groundwater record(s) formed in response to local recharge beneath a wet cany9on floor. Recharge may be enhanced across the Pajarito fault zone where shallow, densely-welded tuffs rocks are highly fractured.
4. Small zones of perched water formed above stratigraphic traps in Puye fanglomerate. these perched zones tend to be more numerous beneath large wet canyons and less frequent beneath dry mesa tops.
5. Perched groundwater associated with Cerros del Rio basalt. Saturation occurs in fractured basalt flows and in interflow breccias and sediments.
6. Perched zones form in response to local geologic conditions on the eastern side of the plateau. These include perched zones within clay-altered tuffaceous sediments and above lake deposits.

Figure 2-37. Conceptual model of groundwater occurrences beneath the Pajarito Plateau.

Identification of perched groundwater systems beneath the Pajarito Plateau comes mostly from direct observation of saturation in boreholes, wells, or piezometers or from borehole geophysics. Additional information is provided by surface-based electrical geophysics, although these types of investigations are generally limited by their relatively shallow depths of investigation and poor vertical resolution. Identification of larger perched groundwater bodies in boreholes is generally reliable, but use of drilling fluids, which is necessary in most boreholes, may mask smaller or relatively unproductive zones. Defining the lateral extent of saturation is more problematical because of the costs associated with installing deep wells. One geophysical method, a deep-sounding surface-based magnetotelluric survey, has been conducted in the Cañon de Valle/Water Canyon area. The survey results suggest that perched groundwater is

discontinuous laterally, occurring instead as vertical, finger-like groundwater bodies. These geophysical interpretations are currently being tested by additional drilling. Despite these limitations, substantial new information has been gathered about deep perched zones on the plateau during the Hydrogeologic Workplan investigations.

This section briefly summarizes the observed occurrences of perched water. Appendix 2-B contains a comprehensive description of the 33 occurrences of perched groundwater detected in boreholes across the Pajarito Plateau. Perched groundwater is widely distributed across the northern and central part of the plateau (Figure 2-38) with depth to water ranging from 36 to 272 m (118 to 894 ft). The principal occurrences of perched groundwater occur in (1) the large, relatively wet Los Alamos and Pueblo Canyon watersheds, (2) the smaller watersheds of Sandia and Mortandad Canyons that receive significant volumes of treated effluent from LANL operations, and (3) in the Cañon de Valle area in the southwestern part of LANL. Perched water is most often found in Puye fanglomerates (Section 2.2.7), the Cerros del Rio basalt (Section 2.2.8), and in units of the Bandelier Tuff (Section 2.2.9) (Figure 2-38). There are few reported occurrences of perched water in the southern part of LANL, but few deep boreholes are located there and additional perched zones are likely beneath the large wet watersheds of Pajarito and Water Canyons.

2.7.2 Interpretation of Perched Water Observations

General conclusions about the nature of perched groundwater beneath the Pajarito Plateau are based on the observations summarized above. The conclusions pertain to surface hydrologic conditions necessary to support perched groundwater, geologic and hydrostratigraphic controls on perched water occurrence, the lateral and vertical extent of perched zones, and alternative hypotheses about the role of perched zones in contaminant transport.

2.7.2.1 Surface Water Conditions for Perched Water

A requirement for deep perched water to exist is a surface water source (natural or anthropogenic) that supplies water to alluvial systems. The alluvial groundwater systems act as storage for groundwater entering underlying bedrock units at high infiltration rates (Section 2.5). This interpretation is supported by the observation of perched groundwater in wet canyons. In addition, ponding associated with anthropogenic sources is another possible water source that could lead to subsurface perched water.

A special situation also exists in the western portion of the Laboratory, in the mountain-front mesa area at TA-16. In contrast to the dry mesas prevalent further east, these mesas receive greater precipitation (e.g., 500 mm/yr) and increased runoff and infiltration. The wet, mountain-front mesas contain numerous perennial and ephemeral springs. Such springs are rare in the dry mesas of the eastern part of the plateau, except where the regional groundwater aquifer discharges along the Rio Grande.

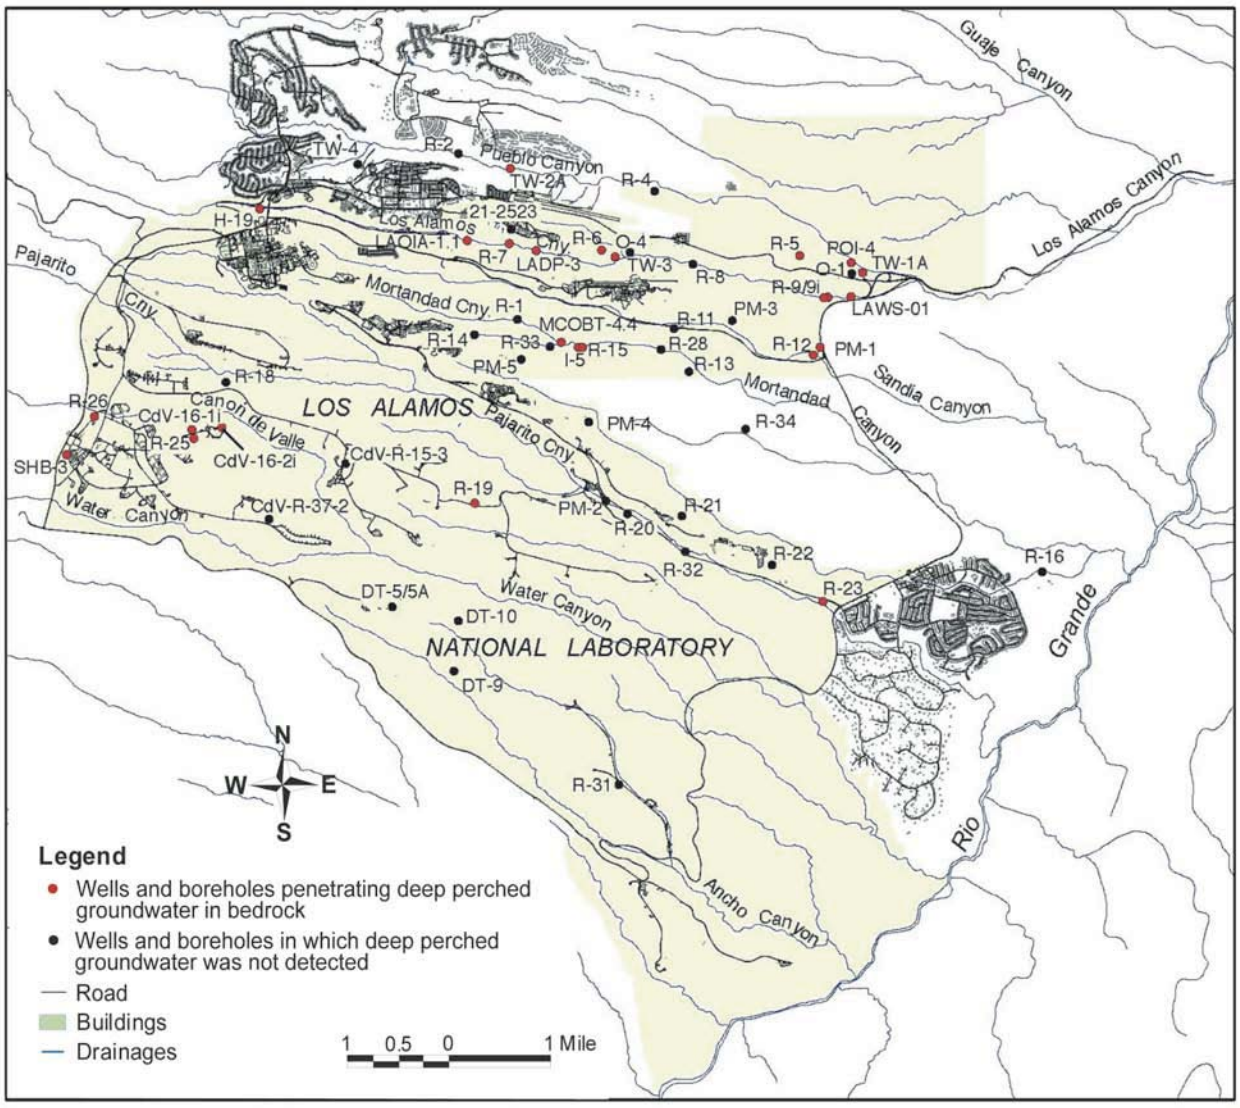


Figure 2-38. Locations of wells and boreholes that have penetrated perched groundwater systems in bedrock.
Note: The area shown in yellow is LANL.

2.7.2.2 Geologic and Hydrostratigraphic Controls on Perched Water Occurrence

Deep perched groundwater occurs most frequently in the Puye Formation (Section 2.2.7) and Cerros del Rio basalt (Section 2.2.8), but some of the thickest and/or most laterally extensive zones involve units of the Bandelier Tuff (Section 2.2.9). Perching horizons include a wide variety of layered geologic lithologies including

- Unfractured basalt flows
- Clay-rich interflow zones in basalt
- Buried soils and other fine-grained deposits in fanglomerate,

- Clay-altered tuffaceous sediments
- Lake deposits.

Therefore, in addition to high local infiltration rates, low-permeability barriers to downward vertical flow appear to be required to induce perched groundwater (Robinson et al., 2005b). In contrast, there have been no observations of perched groundwater caused by a capillary barrier effect, despite the presence of layered stratigraphy with units of contrasting unsaturated flow properties.

An alternative hypothesis is that the deepest perched water occurrences are a manifestation of complex groundwater flow within the phreatic zone at the top of the regional aquifer. Localized heterogeneities, such as the clay-rich alteration zones in the Puye Formation at well R-9, combined with high recharge, may give rise to a complex flow structure that includes mounding, interconnected saturated zones, and locally confined conditions (Robinson et al., 2005b). However, the complexity of the alteration and the depth of these groundwater zones make detailed characterization prohibitively expensive. Hydrologic testing of the regional aquifer could be conducted to discriminate between alternatives.

With respect to the western portion of the Laboratory, Duffy (2004) discusses the importance of mountain-front processes and hydrologic conditions in semiarid landscapes and suggests that the mountain block and mountain-front areas are the dominant recharge zones in semiarid landscapes. An important hydrostratigraphic feature in this area is that the upper tuff units along the mountain front are often moderately to strongly welded because of close proximity to the caldera source. Welding results in increased fracturing during cooling, and because the mountain-front mesas lie within the Pajarito fault zone, additional fracturing and minor faulting of the tuff units has resulted. The welded tuffs create a hydraulic condition where matrix hydraulic conductivities are low (e.g., 10^{-7} to 10^{-9} cm/sec), but fracture densities are relatively high. Thus, there is a possibility for significant fracture flow. Fracturing appears to control locations of springs along the mountain-front mesas and fracture flow is suggested by water content and contaminant distributions in the tuff proximal to outfalls and wastewater lagoons (LANL, 2003b).

2.7.2.3 Subsurface Extent of Zones of Saturation

Observed saturated thicknesses of perched zones vary from 1 to 128 m (3 to 421 ft). The lateral extent of saturation in these zones is less well understood because costs associated with installing deep wells are high. However, perched groundwater generally is more likely to be present beneath wet canyons, based on observations of both occurrences and nearby absences of perched groundwater in adjacent wells. The extent that perched groundwater flows along dipping geologic strata into areas beneath adjacent mesas is not fully known. However, the few paired canyon/mesa wells such as R-7 and 21-2523 in Los Alamos Canyon and R-22 and R-23 in Pajarito Canyon suggest that perched zones are much less common beneath dry mesas.

2.7.2.4 Flow Conditions Upstream and Within Intermediate Perched Groundwater Zones

The presence of mobile (nonsorbing) anthropogenic chemicals in some perched groundwater zones indicates a connection with surface and alluvial groundwater (e.g., Robinson et al., 2005

and references therein). The travel time of groundwater moving from the surface to perched groundwater systems is on the order of several decades, based on the age of facilities that are potential sources of contaminants. Within the perched zones themselves, the topography of the perching horizon, the bedding features, and the orientation of interconnected fracture systems probably control local groundwater flow velocity. However, direct evidence such as single-well or multiple-well hydrologic and tracer testing, is not available. Therefore, the following discussion is based on reasonable hydrologic principles rather than direct measurements.

Flow conditions can, in principle, be categorized with the following two end-member conceptual models for flow within a perched water zone:

- *Low-velocity, virtually stagnant water resting in a perching horizon within a local structural or stratigraphic depression.* Water percolates very slowly out the bottom of this zone, or spills over the sides of the depression. This configuration views perching horizons as barriers that slow the downward percolation of water. In several wells, intermediate saturated zones thought to represent perched groundwater were screened but failed to produce significant water (Robinson et al., 2005). These occurrences may represent cases where zones of limited extent were substantially drained when the perching horizon was penetrated during drilling. Once the stagnant water is depleted in an initial round of sampling, there is insufficient recharge to keep the zone saturated.
- *High-velocity, laterally migrating fluid that travels on top of the perching horizon.* This conceptualization suggests that once groundwater reaches a perched zone, it rapidly percolates laterally along high-permeability pathways until the perching horizon pinches out or is breached by high-permeability features such as fractures or lateral changes in lithology. In this scenario, water could move in stairstep fashion from one perching horizon to another. There are no confirmed instances of large-scale, lateral vadose zone pathways beneath the Pajarito Plateau at depths greater than the alluvial groundwater. The case of lateral flow through the wet, mountain-front mesas at TA-16 suggests that this possibility exists at greater depths. Although we categorize the TA-16 observations as shallow for the purposes of this discussion because they discharge via springs in the local canyons, it could be argued that deep pathways with flow geometries similar to those of the mountain-front mesa or today's alluvial groundwater zones are evidence for the possibility of deeper fast pathways elsewhere.

Tracer experiments in alluvial and mountain-front mesa perched zones have been used to measure transport velocities. However, fluid velocity in the deeper perched groundwater zones is unknown due to the lack of direct measurements. The two end-member conceptual models, relatively stagnant fluid in a local subsurface depression, or lateral diversion in the hydrologic unit overlying the perching horizon, cannot be ruled out with existing data. Hydrologic, tracer, or remote geophysical techniques would be required to shed light on this question. Given the complexity and cost of such field campaigns, they should be performed only if model sensitivity analyses indicate that sorting out this issue is important to study impacts, or if remediation of a perched zone is to be conducted.

2.8 Regional Aquifer Conceptual Model

This section summarizes the current understanding of flow and transport in the regional aquifer beneath the plateau. This work builds on results obtained from earlier hydrologic studies in the region (Griggs and Hem, 1964; Purtymun, 1984; Purtymun and Johansen, 1974; Rogers et al., 1996b). The previous literature is supplemented with interpretations of new data collected by the LANL Groundwater Protection Program. These new data, combined with previous studies, provide the foundation for the flow and transport model development presented in Section 4.2

2.8.1 Regional Hydrologic Setting

This section briefly summarizes the regional hydrologic setting before focusing on the regional aquifer beneath the Pajarito Plateau (Section 2.7.2), which is the subject of this report. The Española Basin (see Figure 2-39) is one of a series of basins located within the Rio Grade Rift zone, a tectonic feature that extends from northern Colorado to the south into Mexico. Elevations within the basin range from more than 3,800 m along peaks in the surrounding mountain ranges to about 1,700 m at the basin surface water outlet. Vegetation is predominantly ponderosa pine forest at higher elevations and piñon pine/ juniper at lower elevations (Spiegel and Baldwin 1963).

The Española Basin and surrounding areas receive annual total precipitation ranging from 18 to 86 cm/yr. Precipitation is strongly elevation dependent (Spiegel and Baldwin 1963). The largest streams in the basin are the Rio Grande and Rio Chama. Median monthly flow, calculated using USGS average monthly flow data for the past 80 years, is 26.0 m^3/s along the Rio Grande (at Otowi Bridge) and 10.0 m^3/s along the Rio Chama (at Chamita) (U.S. Geological Survey, 2001). Numerous tributaries enter these rivers; many of these are ephemeral and many are ungaged. The Rio Grande and the lower reaches of many tributaries comprise the regional groundwater discharge zone.

In most parts of the basin, the water table is 0–60 m below ground surface; but on the Pajarito Plateau the water table is much deeper (up to 350 m below the surface). Throughout much of the basin, the water table appears to intersect the surface at the Rio Grande (Purtymun, 1984). Perched waters exist on the Pajarito Plateau (Robinson et al., 2005) where the unsaturated zone is much thicker than in other parts of the basin (Section 2.7). Contours of predevelopment water level data (Purtymun et al., 1995a, 1995b; U.S. Geological Survey, 1997) indicate that hydraulic gradients are generally towards the Rio Grande (Figure 2-40).

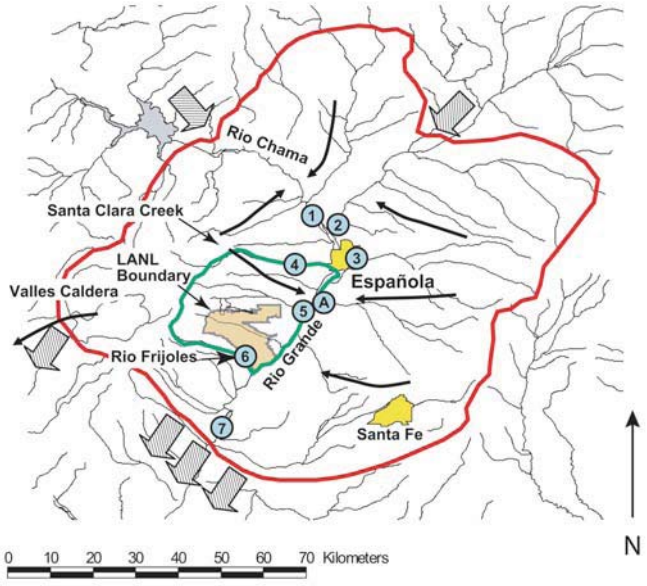

Figure 2-39. The Española Basin and vicinity, with basin-scale numerical model outline shown in red, site-scale model outline shown in green. Black arrows are generalized groundwater flow directions, based on regional water level data (Keating et al., 2003). The striped arrows indicate groundwater flow between the Española Basin and adjacent basins. Circled numbers refer to USGS stream gages: (1) Rio Chama at Chamita; (2) Rio Grande at San Juan; (3) Santa Cruz River; (4) Santa Clara Creek; (5) Rio Grande at Otowi; (6) Rio Frijoles; (7) Rio Grande at Cochiti. Circled "A" indicates the mouth of the Pojoaque Creek.

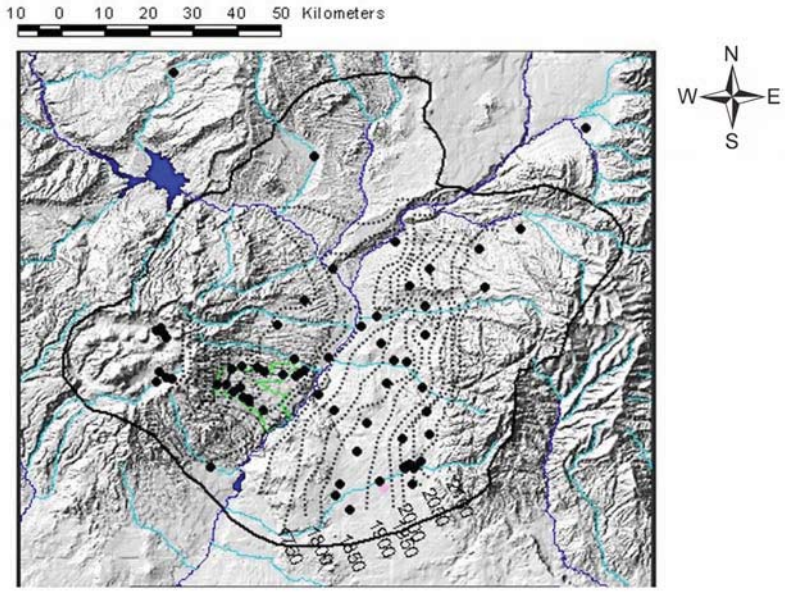

Figure 2-40. Approximation to present-day water table elevations (m).
Note: Some older head data are used to improve the spatial distribution.

The regional aquifer is a major source of drinking water and agricultural water supply for northern New Mexico. The largest cities in the basin are Santa Fe, Española, and Los Alamos; these all rely primarily on groundwater for municipal supply. In addition to discharges to water supply wells, the aquifer discharges to the Rio Grande, the lower reaches of its tributaries, and to numerous springs. There are additional withdrawals for municipal and agricultural supply. Recharge is thought to occur primarily in the higher elevations—estimates based on water budget and chloride mass balance methods range from 7–26% of total precipitation (Anderholm, 1994; Wasiolek, 1995). Little or no recharge occurs at lower elevations other than along stream channels due to low precipitation rates and high evapotranspiration demand (Anderholm, 1994).

The aquifer is predominantly composed of Santa Fe Group rocks, which are weakly consolidated basin-fill sediments reaching over 3,000 m in thickness near the basin axis (Cordell 1979). Groundwater also occurs in older crystalline rocks along the eastern and northern basin margin and in younger volcanic lavas and volcaniclastic sedimentary rocks in the vicinity of the Pajarito Plateau to the west (Purtymun and Johansen, 1974; Coon and Kelly, 1984; Daniel B. Stephens & Associates, 1994).

2.8.2 Hydrology Beneath the Pajarito Plateau

Groundwater beneath the Pajarito Plateau is part of a regional aquifer which extends throughout the Española Basin (an area roughly 6000 km^2; Figure 2-39). This aquifer is the primary source of water for the Laboratory, the communities of Santa Fe, Española, Los Alamos, and numerous pueblos. Four water supply wellfields exist on the plateau (Figure 2-41); one additional wellfield that supplies the city of Santa Fe (Buckman) sits just to the east of the Rio Grande, close to the plateau. As is the case for many aquifers in the semiarid southwest, there is concern that current withdrawal rates may not be sustainable over long periods of time and current drought conditions might have significant impacts on both surface water and groundwater quantity and quality.

Of more direct relevance to the Hydrogeologic Workplan studies are concerns about water quality, due to a variety of anthropogenic contaminants. Beneath the Pajarito Plateau, there is contamination from various LANL sources in shallow groundwaters in some locations (primarily alluvial aquifers). Some of the LANL-derived contamination has been observed in the regional aquifer at trace concentrations much below the EPA drinking water standards (see Section 3 for a complete discussion of this point). The regional aquifer is the groundwater zone most directly accessible to humans through municipal water-supply wells or springs issuing to the Rio Grande. Therefore, a solid foundation of understanding of the hydrogeologic conditions and controls on flow and transport in the regional aquifer must be obtained in order to make risk-based decisions, to design the required groundwater monitoring network, or to design treatment and remediation systems.

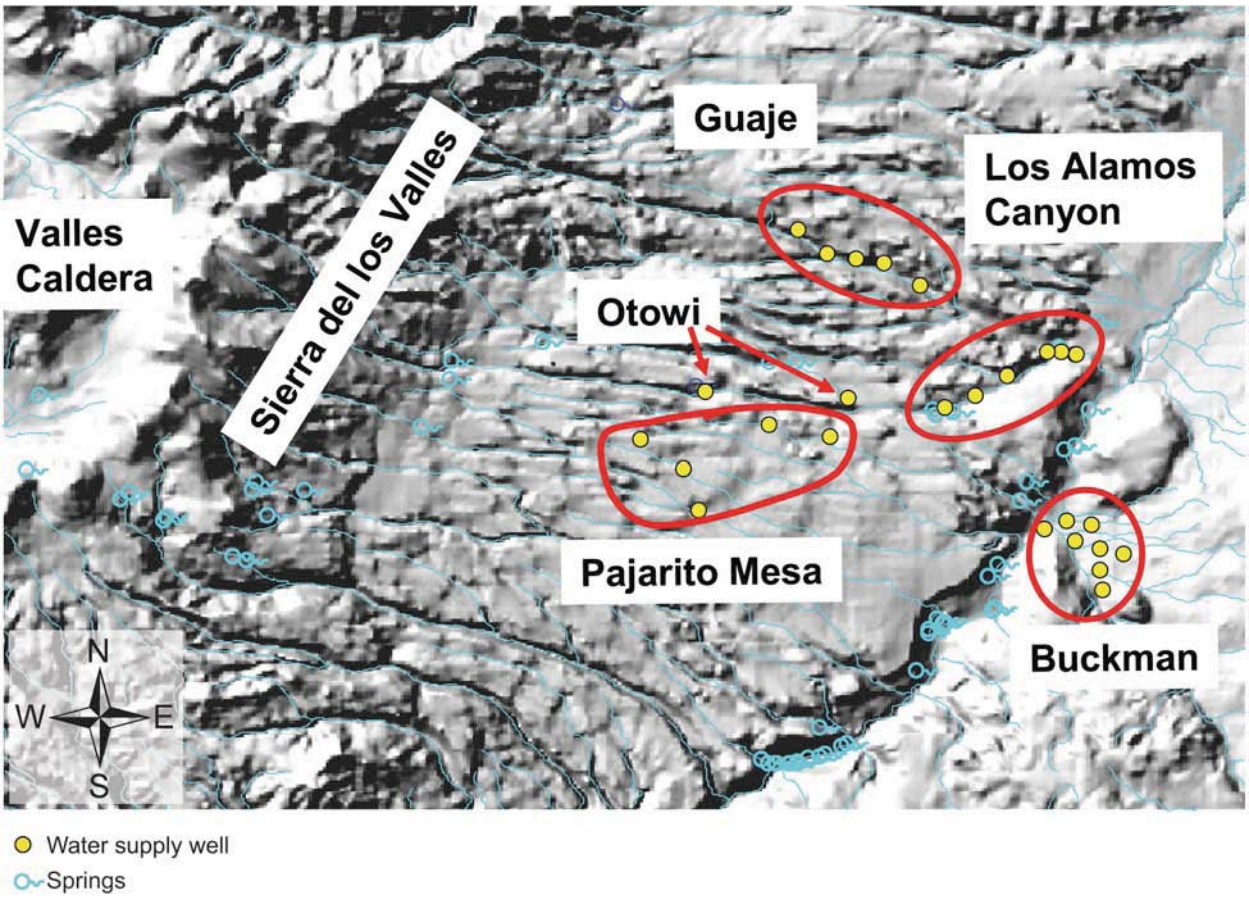

Figure 2-41. The Pajarito Plateau, with major wellfields indicated by enclosures in red.

2.8.3 Water Budget

The water budget for the regional aquifer defines the sources and sinks of water to and from the Española Basin and, on a smaller scale, under the Pajarito Plateau. This section summarizes the state of knowledge and addresses uncertainties in the quantities and spatial distribution of recharge, discharge, and interbasin flow.

2.8.3.1 Recharge

As the water source term, recharge to the regional aquifer provides the driving force for fluid movement through the system. Furthermore, water recharging on the Pajarito Plateau on LANL property can carry with it liquid-borne contamination. This subsection addresses both basin-scale and local recharge, addressing the spatial distribution and quantity of recharge.

2.8.3.1.1 Recharge Distribution

Various theories have been proposed regarding the locations of recharge zones for this aquifer. Griggs (1964) suggested that most of the recharge occurred in the Sierra del los Valles and along stream channels in the western edge of the Pajarito Plateau (Figure 2-41). Purtymun and Johansen (1974) proposed that the major portion of the recharge occurs in the Valles Caldera, with smaller amounts recharging through stream channels in the Sierra del los Valles. However, Blake et al., (1995) argued that recharge could not originate in the Valles Caldera, since the

chemistry of geothermal waters in the western Valles Caldera is clearly distinct from the groundwaters on the Pajarito Plateau (Blake et al., 1995; Goff and Sayer, 1980). These authors also proposed, on the basis of stable isotope values in groundwaters beneath the plateau, that recharge areas for the aquifer beneath the plateau were either to the north and/or to the east (Sangre de Cristo Mountains) and not to the west. They hypothesized that the two flow systems are separated by the Pajarito fault acting as a flow barrier (Blake et al., 1995).

In contrast, other lines of evidence indicate that the majority of recharge to the basin aquifer occurs in the mountains along the basin margin where precipitation rates are relatively high. This has been shown using water-budget and chloride-mass balance analyses in the eastern portion of the basin (Anderholm, 1994; Wasiolek, 1995). In the course of the Hydrogeologic Workplan studies, inverse modeling using head and streamflow data (Keating et al., 2003) demonstrated that the elevation above which significant recharge occurs at the basin-scale is very well constrained (2195m ± 177m). Modeling results such as this are to some extent a function of the model conceptualization and structure, and therefore do not provide a precise indication of the recharge elevation. Nevertheless, the modeling result agrees with the conclusion on the elevation above which recharge occurs, as determined from those other lines of evidence.

Isotope geochemical information can also be brought to bear on the question of recharge distribution. Distributions of δD and $\delta^{18}O$ ratios are consistent with the conclusion that the mountain front recharge supplies most of the groundwater beneath the Pajarito Plateau (Longmire, 2002a; Longmire, 2002b; Longmire, 2002c; Longmire, 2002d; Longmire, 2002; Longmire and Goff, 2002). Lighter or more negative δD and $\delta^{18}O$ ratios indicate both a cooler climate for precipitation and/or a higher elevation of recharge (Clark and Fritz, 1997). Heavier or less negative δD and $\delta^{18}O$ ratios are representative of a warmer climate for precipitation and/or recharge that occurs at lower elevations. Groundwater samples collected within the Sierra de los Valles have lighter δD and $\delta^{18}O$ ratios relative to those collected beneath the Pajarito Plateau and along the Rio Grande. Precipitation of meteoric water at higher elevations, for example near the Sierra de los Valles, is characterized by cooler temperatures relative to other waters found at lower elevations on the Pajarito Plateau. Long-term temperatures (paleotemperatures) and seasonal variations in temperature also influence $\delta^{18}O$ and δD values because of enrichment or depletion of oxygen-18 and deuterium (Clark and Fritz, 1997).

A plot of δD versus $\delta^{18}O$ (average values) for numerous groundwater samples collected from wells R-9, R-12, R-15, R-19, R-25, R-26, CdV-R-37-2, and CdV-R15-3 and springs within the Valles caldera and Sierra de los Valles is shown in Section 3.1.1.1. In this figure, the Jemez Mountains meteoric line (upper) ($\delta D = 8\delta^{18}O + 12$) (Vuataz et al., 1986) and the mean worldwide meteoric water line (lower) (($D = 8\delta^{18}O + 10$) (Clark and Fritz, 1997) are denoted by JMML and MWL, respectively. Analytical uncertainties of $\delta^{18}O$ and δD are ± 0.1 and ± 1‰ (per mil), respectively. Results of stable isotope analyses for the R wells and springs indicate a meteoric source in which the samples plot close to both the JMML and MWL (Section 3.1.1.1). The distribution of isotopic ratios suggests that evaporation of groundwater has not taken place to a significant extent prior to recharge.

The Sierra de los Valles is the likely recharge source for wells R-25, R-26, CdV-R-15-3, CdV-R-37-2 because the Sierra de los Valles springs have similar $\delta^{18}O$ and δD ratios (Blake et al. 1995).

The less negative stable $\delta^{18}O$ and δD values (relative to well R-25) in wells R-9, R-12, R-15, and R-19 are consistent with additional recharge at lower elevations (Section 3.1.1.1). This interpretation is consistent with the concept of local recharge on the plateau as the source for water at shallow depths in the regional aquifer beneath the Laboratory.

Although analyses such as these can be useful in identifying the elevation of recharge, Keating et al. (2005) point out that uncertainties due to variability in isotopic composition of precipitation and potential differences in precipitation and infiltration elevations complicate the use of these isotopic tracers. For example, stable isotope ratios may actually be tracing the *timing* of recharge for very old waters (Phillips et al., 1986), as opposed to the location. Very low $\delta^{18}O$ values (< -14), significantly lower than average modern precipitation signatures at all elevations in the basin, have been measured in groundwaters near the Rio Grande (Anderholm, 1994; Blake et al., 1995). These ratios are indicative of paleorecharge during a cooler climate (Phillips et al., 1986) and were interpreted by Anderholm (1994) and Newman (1996) to indicate recharge during the Pleistocene (with age in order of 8,000 – 17,000 years). These age estimates are consistent with ^{14}C observations suggesting a component of old fluid (Rogers et al., 1996b). Note however that some of these same waters also clearly contain a component of young water, as indicated in Section 3.1.1.3.

A quantitative assessment of the spatial distribution of recharge on the Plateau was recently published by Kwicklis et al. (2005). The goal of the study was to provide a summary of the current state of knowledge on amount and spatial distribution of infiltration. The study was intended to provide quantitative estimates for use in other studies, as well as to provide a baseline that can be tested and improved upon as more data are collected. The study uses streamflow gain and loss data along canyon bottoms from the Pajarito Plateau, along with point infiltration estimates based on moisture content profiles interpreted using the Richards equation, the chloride mass-balance method, transport rates of tritium in canyons on the Plateau, and numerical modeling. The infiltration rates estimated with these techniques were extrapolated to uncharacterized parts of the study area using maps of environmental variables that are correlated with infiltration (such as topography, vegetation cover, and surficial geology and structure) and spatial algorithms implemented with GIS software that use the mapped variables.

The map of estimated infiltration is presented in Figure 2-34. The large-scale characteristics of these estimates are in line with the discussion presented above. Infiltration rates throughout most of the plateau are generally less than 2 mm/yr, whereas infiltration rates in the mixed conifer-dominated areas of the Sierra de los Valles are typically greater than 25 mm/yr and, in the aspen-dominated areas, greater than 200 mm/yr. Thus, at lower elevations, recharge occurs primarily along arroyos and canyons, and infiltration rates are estimated to be low on mesas except near the mountain front (Anderholm, 1994; Birdsell et al., 2005). Despite the low flux, the total quantity of infiltration associated with the mesas is small but not negligible, due to the large area associated with these parts of the plateau.

The Kwicklis et al. (2005) study estimates that of the total infiltration of about 8600 acre-ft/yr (336 kg/sec), about 23% of the infiltration occurs from canyon bottoms on the plateau at lower elevations. This canyon-bottom infiltration includes about 14% of the total from streams that flow at least partly within LANL boundaries. The inserts in Figure 2-34 indicate regions for

which localized, high-infiltration zones are expected to exist on the plateau. Focused infiltration is expected in the faulted regions associated with the Pajarito fault zone within Cañon de Valle and Water Canyon (see lower left insert in Figure 2-34). Local infiltration at rates up to 1000 mm/yr is estimated. For the insert showing the confluence of Los Alamos and Pueblo Canyons (lower right), rates of 1500–2000 mm/yr are estimated in this region. These high values are a consequence of infiltration directly onto Puye fanglomerates or fractured basalts. In other canyons with similar characteristics, such as Pajarito Canyon, similarly high local infiltration values are expected.

Although relatively small volumetrically compared to mountain recharge to the west, aquifer recharge occurring locally on the plateau is important to the assessment of flow paths of potentially contaminated water. Tritium data confirm that relatively young water is present in the aquifer (Rogers et al., 1996b), indicating fast pathways through the vadose zone beneath LANL. Quantitative estimation of recharge using ^{3}H data is complicated by the sometimes confounding influences of bomb-pulse atmospheric ^{3}H and locally derived ^{3}H related to on-site LANL activities. Elevated ^{3}H in regional aquifer samples has been observed at O-1, TW-1, TW-3, TW-8, LA-1A and LA-2 (Rogers et al., 1996b), as well as in several wells drilled during the more recent characterization drilling program (see Section 3.3).

Kwicklis et al. (2005) used vadose zone occurrences of ^{3}H to estimate the time-dependent transport velocities, from which they derived infiltration rates to the regional aquifer. They found that in Mortandad Canyon, infiltration rates are as high as 2000 mm/yr occur during periods of large volumes of effluent discharge. This infiltration rate has apparently decreased to 100-200 mm/yr once effluent discharge flow rates were reduced. These observations and analysis confirm that local recharge in canyons is an important component of the recharge distribution for the plateau.

2.8.3.1.2 Total Recharge

Estimates of total recharge provide important constraints on flow and transport models of the regional aquifer by tying model calibrations to measured or estimated water balance components. Therefore, various techniques and data sets have been examined to estimate total recharge. Griggs (1964) estimated the total recharge to the aquifer beneath the Plateau to be between 168 and 216 kg/s. McLin et al. (1996) estimated an upper bound of 192 kg/s, based on recovery of water levels in supply wells rested for a period of several months to several years. Using a variety of methods and considering a larger area, the Kwicklis et al. (2005) study discussed above estimates total average annual recharge to the Pajarito Plateau of 336 kg/sec.

A number of researchers have used baseflow gain to the Rio Grande to estimate total aquifer discharge, from beneath both the plateau and the eastern basin. These estimates presumably approximate the total aquifer recharge before significant pumping began. However, total gain must be combined with an estimate of the proportion of the gain that originates beneath the plateau. Long-term average aquifer discharge between the Otowi Bridge gage and the now-submerged Cochiti gage, a reach which bounds the southern portion of the plateau, was estimated by Spiegel and Baldwin (1963) to be 710 kg/sec and more recently by the U.S. Department of Justice to be 400 kg/sec (U.S. Department of Justice and New Mexico State Engineer Office, 1996). The former estimate is significantly higher because the authors did not

include years of record that indicated the reach to be losing, which was attributed to measurement error. Keating et al. (2005) present an analysis of data from this reach as well as the reach immediately to the north (Española to Otowi), which bounds the northern portion of the plateau. This analysis estimates the total gain to the Rio Grande adjacent to the Pajarito Plateau (Santa Clara Creek to Rio Frijoles) to be approximately 911 kg/sec (+/– 30%). The modeling study of Hearne (1985) assumes 316 kg/sec recharge to the Pajarito Plateau; McAda and Wasiolek (1988) assume 291 kg/sec lateral inflow from the Jemez Mountains.

Aquifer modeling studies can also shed light on the recharge quantities and distribution. Keating et al. (2003) performed basin-scale inverse modeling as part of the Hydrogeologic Workplan, using both streamflow data and transient head data. That study indicated that approximately 253 kg/sec of the gain to the river along this reach originated on the Pajarito Plateau and the Sierra de los Valles. This analysis probably underestimated total recharge on the plateau, in part because the basin model was calibrated to a lower estimate of aquifer discharge north of Otowi Bridge than is indicated by the streamflow analysis subsequently performed by Keating et al. (2005). Part of the reason for the differences between these various estimates of total recharge is that several of the smaller estimates (McLin et al., 1996; Speigel and Baldwin, 1963; and Griggs 1964) emphasized the southern portion of the plateau (including LANL) which, according to the streamflow analysis in Keating et al. (2005), is discharging less water than the northern portion of the plateau.

In summary, although these various estimates span a range and reflect some uncertainty, they are extremely valuable as bounding values for flow and transport modeling in that they constrain the total quantity of water flowing through the aquifer beneath the Pajarito Plateau.

2.8.3.2 Discharge

Data constraining quantity of discharge for the regional aquifer were discussed in Section 2.8.3.1 in the context of estimating recharge. Regarding discharge locations, many authors have identified the Rio Grande as the principal discharge point for the regional aquifer (Cushman, 1965; Griggs and Hem, 1964; Hearne, 1985; McAda and Wasiolek, 1988; Purtymun and Johansen, 1974; Theis and Conover, 1962). Previous reports have cited a variety of evidence to support this, including:

- Streamflow gain along the Rio Grande (Balleau Groundwater, 1995; Purtymun and Johansen, 1974; Spiegel and Baldwin, 1963)
- Measured vertical upward gradients in the vicinity of the Rio Grande (Cushman, 1965; Griggs and Hem, 1964)
- The presence of flowing wells (McAda and Wasiolek, 1988; McLin et al., 1996; Spiegel and Baldwin, 1963)
- Springs along the river (McLin et al., 1996).

Discharge to the river may occur as lateral flow, upward flow, or as flow from springs in White Rock Canyon. Purtymun (1966) suggested that all the springs, which collectively flow approximately 85 kg/sec, discharge water from the upper surface of the main aquifer. Stone (1996) suggested that many of these springs may be discharging perched aquifers rather than the regional aquifer; unfortunately it is difficult to test these alternative hypotheses, although stable

isotopes may provide some discrimination. It has been emphasized that although discontinuous, low-permeability beds produce confining conditions in the aquifer locally near the Rio Grande and elsewhere in the basin, flow is able to cross the low permeability beds in some locations as water discharges to the river (Hearne, 1985; Spiegel and Baldwin, 1963).

The degree of connection between the aquifer and the Rio Grande has been investigated by Balleau Groundwater (1995), who drilled 16 wells in the alluvial aquifer of the Rio Grande near the Buckman wellfield and conducted pumping tests. They found that head in the alluvium is generally 0.1 to 0.2 feet higher than the Rio Grande, indicating discharge from the alluvium to the Rio Grande. Head in the regional aquifer below the alluvium, at a depth of 59 feet, is about 2.8 feet higher than the Rio Grande. From pumping tests, they concluded that the hydrogeologic system at the site behaves as a layered water-table system in hydraulic contact with the river with delayed yield from pore-water storage and an adjacent river boundary source.

2.8.3.3 Interbasin Flow

Overall groundwater fluxes between the regional aquifer beneath the plateau and the basin and flow between the Española Basin and adjoining basins are not well constrained. It is possible that virtually all the groundwater flowing beneath the Pajarito Plateau flows easterly/southeasterly and discharges to the Rio Grande, and that interbasin flow to the south is small. An alternative possibility, that deep flow discharges instead to the basins to the south, is difficult to confirm or refute because of the lack of hydraulic data collected at discrete intervals at great depths within the aquifer. This could have a large impact on flow conditions at and near the site and thus will be the subject of future study.

The Española Basin is separated from the Albuquerque and Santo Domingo basins to the south by a structural high, a prong of older sedimentary rocks, and several major fault zones (Golombek et al., 1983). The Santa Fe Group aquifer thins significantly at this boundary (Shomaker, 1974). If these structures impede flow to the south, this might enhance both regional aquifer and interflow discharge to the surface. We have not evaluated the possible interflow component to streamflow gain in the southern portion of the basin; if it were significant our estimate of groundwater discharge would be erroneously high.

Numerical models of groundwater flow in the basin have generally predicted the interflow component of flow to the south to be small. The model of Hearne (1985) has no groundwater flow to the south by assumption; the McAda and Wasiolek (1988) and Keating et al. (2003) models allow interflow, but the models predict much larger discharge within the basin (to the Rio Grande) than to basins to the south. For example, Keating et al. (2003) estimated southerly flow from the Pajarito Plateau aquifer to the south to be approximately 9 kg/sec. Uncertainty analysis showed a possible range of values + 34 kg/sec or – 62 kg/sec. All of these values are relatively small compared to the total flow to the Rio Grande.

Regarding basin boundaries to the north and west, fluxes entering the region beneath the plateau were estimated by Keating et al. (2003), using basin-scale head and streamflow data and inverse modeling analysis. They estimated that flow into the plateau from the north was very small or zero, with a relatively large degree of certainty. Inflow from the west (Valles caldera) and outflow to the south is more uncertain, and could be as low as zero or as high as 94 or 34 kg/s,

respectively. These fluxes are relatively small compared to estimates of total recharge for the plateau.

These modeling results, when combined with recharge and streamflow estimates, result in a self-consistent mass balance on water moving through the aquifer. Given the uncertainties in the individual flow estimates and the inherent difficulty of defining the appropriate structural features for a large-scale model, it is possible that other conceptualizations would provide equally valid representations of the available information. For example, it is possible that a conceptualization in which more water flows from the Española Basin to the adjoining Albuquerque Basin, rather than discharging at the Rio Grande, would prove valid. Elements of such a model conceptualization are (1) less flow restriction to the south; (2) more restricted flow from the deeper, confined aquifer to the Rio; and (3) southerly flow of a fraction of the deeper aquifer from the Sierra de los Valles and the Sangre de Cristo Mountains to the south. Of course, such a conceptualization would also need to be consistent with the available water budget information. The point here is that alternate conceptualizations such as this cannot be unequivocally ruled out and thus should be considered in future numerical models developed for the plateau and the basin.

2.8.4 Aquifer Hydrologic Properties

This subsection briefly summarizes the hydrologic properties of the regional aquifer rocks. A more detailed treatment of this critical topic, including statistical and spatial distributions of hydraulic conductivities measured in aquifer tests, is presented in Section 2.4. The aquifer beneath the plateau consists of the fractured crystalline rocks of the Tschicoma Formation, Cerros del Rio basalts, and older basalt flows, as well as the sedimentary rocks of the Puye Formation and the Santa Fe Group. These units are described in detail in Section 2.1, as well as by Broxton and Vaniman (2005). Both the Santa Fe Group and the Puye Formation are alluvial fan deposits with alternating beds of high and low permeability, with north-south trending faults associated with basin-scale rifting (Kelley, 1978).

Permeability estimates for the Santa Fe Group are primarily derived from pumping tests in water supply wells screened over large intervals; estimates range from 10^{-11} to $10^{-12.8}$ m^2 (Griggs and Hem, 1964; Purtymun, 1995; Purtymun et al., 1995a; Theis and Conover, 1962). Testing of monitoring wells, with relatively short screens completed within the Puye Formation, has shown very large variability (10^{-11} to $10^{-13.5}$ m^2). The basalt flows beneath the plateau include massive, fractured lava units, breccia zones, and inter-flow zones with significant clay content. Permeability within the Cerros del Rio basalts ranges from $10^{-11.2}$ to $10^{-13.8}$ m^2 (Nylander et al., 2002). Testing at R-28 shows the upper bound of permeability to be between $10^{-10.5}$ and $10^{-10.2}$ m^2 (Kleinfelder, 2004b).

Several estimates of specific storage (Ss) have been derived from various pumping tests: $10^{-4.8}$ /m in the Los Alamos Canyon wellfield (Theis and Conover, 1962); $10^{-5.5}$/m and $10^{-3.8}$/m in the Otowi wellfield (Purtymun et al., 1990; Purtymun et al., 1995b). These relatively low values are indicative of confined or leaky-confined conditions at the depth that these observations were made. This point is expanded upon in the next subsection, along with more recent estimates of specific storage based on a pumping test conducted as part of the Hydrogeologic Workplan.

2.8.5 Anisotropy and Scale Dependence

Both the Santa Fe Group and the Puye Formation are, at least locally, strongly anisotropic. Pumping tests have confirmed that permeability normal to bedding is much lower than permeability parallel to bedding, both on the Pajarito Plateau (McLin et al., 2005; Purtymun et al., 1990; Purtymun et al., 1995b; Stoker et al., 1989) and elsewhere in the basin (Hearne, 1980). Estimates of anisotropy (ratio of vertical to horizontal hydraulic conductivity) vary from 0.00005 (Hearne (1980), pumping test analysis) to 0.04 (Hearne (1980), hydraulic gradient analysis), to 0.01 (McAda and Wasiolek, 1998).

Effective permeability and anisotropy at large spatial scales are difficult to estimate. Many authors have noted the lack of spatial continuity of low or high permeability beds with the Santa Fe Group (Hearne, 1980; Spiegel and Baldwin, 1963; Theis and Conover, 1962) and the difficulty of correlating geophysical or lithologic logs between even closely spaced wells (Cushman, 1965; Shomaker, 1974). Hearne (1980) notes that because of limited spatial continuity in low or high permeability rocks, under a regional pressure gradient vertical flow will occur through circuitous routes and thus effective anisotropy may be less pronounced at large spatial scales than that measured at small scales during pumping tests.

Large-scale, multiple-observation-well aquifer pumping tests are invaluable to examine scale effects and to estimate the impacts of water supply well pumping on pressure gradients in the aquifer. As part of the characterization program, a 25-day aquifer test was conducted at municipal water supply well PM-2 from February 3–28, 2003 (McLin, 2005). The pumping phase was conducted at a constant discharge rate of 1,249 gpm, followed immediately by a 25-day recovery period. Surrounding observation wells were used to record both drawdown and recovery in response to pumping at PM-2. The PM-2 well draws water from a continuous louvered screen between 1,004 and 2,280 ft below ground surface (bgs). Prior to the start of the test, production wells in the vicinity were completely shut down so that hydrostatic conditions in the regional aquifer could recover and a static baseline could be established. Except for the test pumping at PM-2, all of the surrounding water supply wells remained off throughout the test period. Continuous water-level responses to pumping at PM-2 were recorded by transducers that were placed in municipal wells PM-2, PM-4, and PM-5 and in characterization wells R-20 (three separate screens) and R-32 (three separate screens). Periodic responses to pumping were also recorded in characterization wells R-15 (one screen), R-21 (one screen), and R-22 (five separate screens); however, no significant drawdown values were recorded in these latter wells.

Figure 2-42 (from McLin, 2005) shows a layout of PM-2 and nearby monitoring locations during the test. Individual drawdown and recovery water levels in responsive wells demonstrate that the regional aquifer surrounding PM-2 is vertically anisotropic with pronounced resistance to vertical propagation of drawdown at shallower depths. Hydraulically, the aquifer behaves like a semiconfined aquifer at depth with leaky units located above (and perhaps below) a highly conductive layer that averages about 850 ft in thickness. Drawdown in this highly permeable unit was recorded more than 8,800 ft away in well PM-5, while drawdown only 1,225 ft away at the R-20 multiple-screened well was directly related to individual screen depth (Figure 2-43a, from McLin, 2005); the shallowest screen at R-20 showed little drawdown, while the deepest screen

showed a dramatic response to pumping at PM-2. Similar but more subdued behavior was also recorded 4,457 feet away in the R-32 multiple screened well (Figure 2-43b). In contrast, no recordable drawdown was recorded 8,900 feet away in the R-22 multiple screened well, suggesting that an idealized radius of influence for pressure responses due to pumping at PM-2 was at least 8,800 feet after 25 days of continuous pumping. The idealized radius of influence shown in Figure 2-42 is schematic, based on the available data and is not meant to imply that the pressure response spreads uniformly in all directions.

A schematic diagram proposed by McLin (2005) to interpret the aquifer-pumping test and to estimate hydrologic parameters is reproduced in Figure 2-44. Clearly, this aquifer configuration is highly idealized, in that a single, well-defined semi-confining layer has not been identified, and layered heterogeneities certainly exist within the zone depicted as the deeper aquifer (for example, see the geologic cross section of Figure 3 in McLin, 2005). Nevertheless, using this idealized aquifer configuration, McLin (2005) estimated hydraulic conductivity at the scale of this test to be about 5.0 ft/day (based on an assumed aquifer thickness of 850 ft), with a storage coefficient ranging from about 0.00032 to 0.002. Finally, the observations of muted drawdown at observation points near the water table (significantly above the pumping elevation) suggest that the horizontal-to-vertical anisotropy ratio of hydraulic conductivities is highly variable: McLin (2005) suggests that the ratio of vertical to horizontal hydraulic conductivity may be on the order of 0.01 in some locations within the regional aquifer.

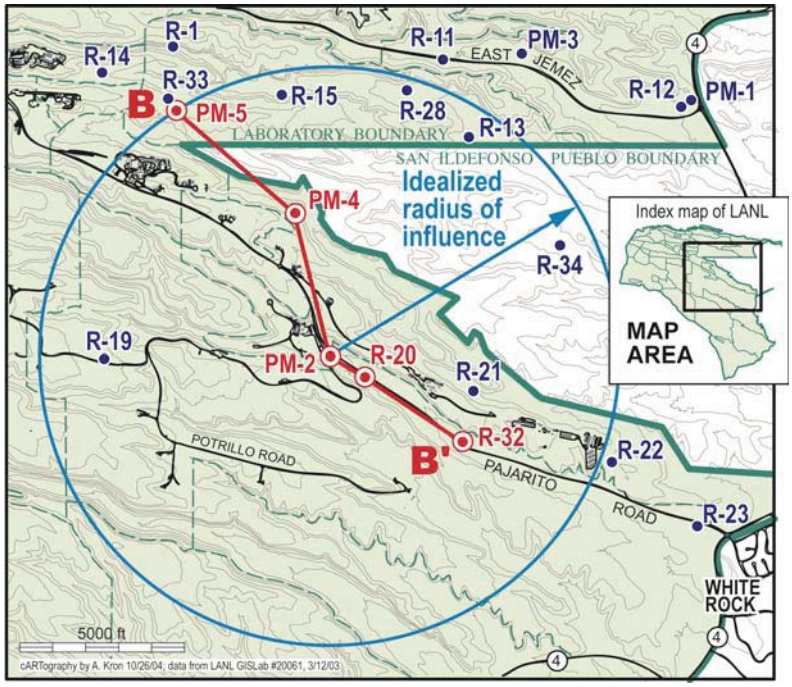

Figure 2-42. Idealized radius of influence of PM-2 on surrounding wells (McLin, 2005).

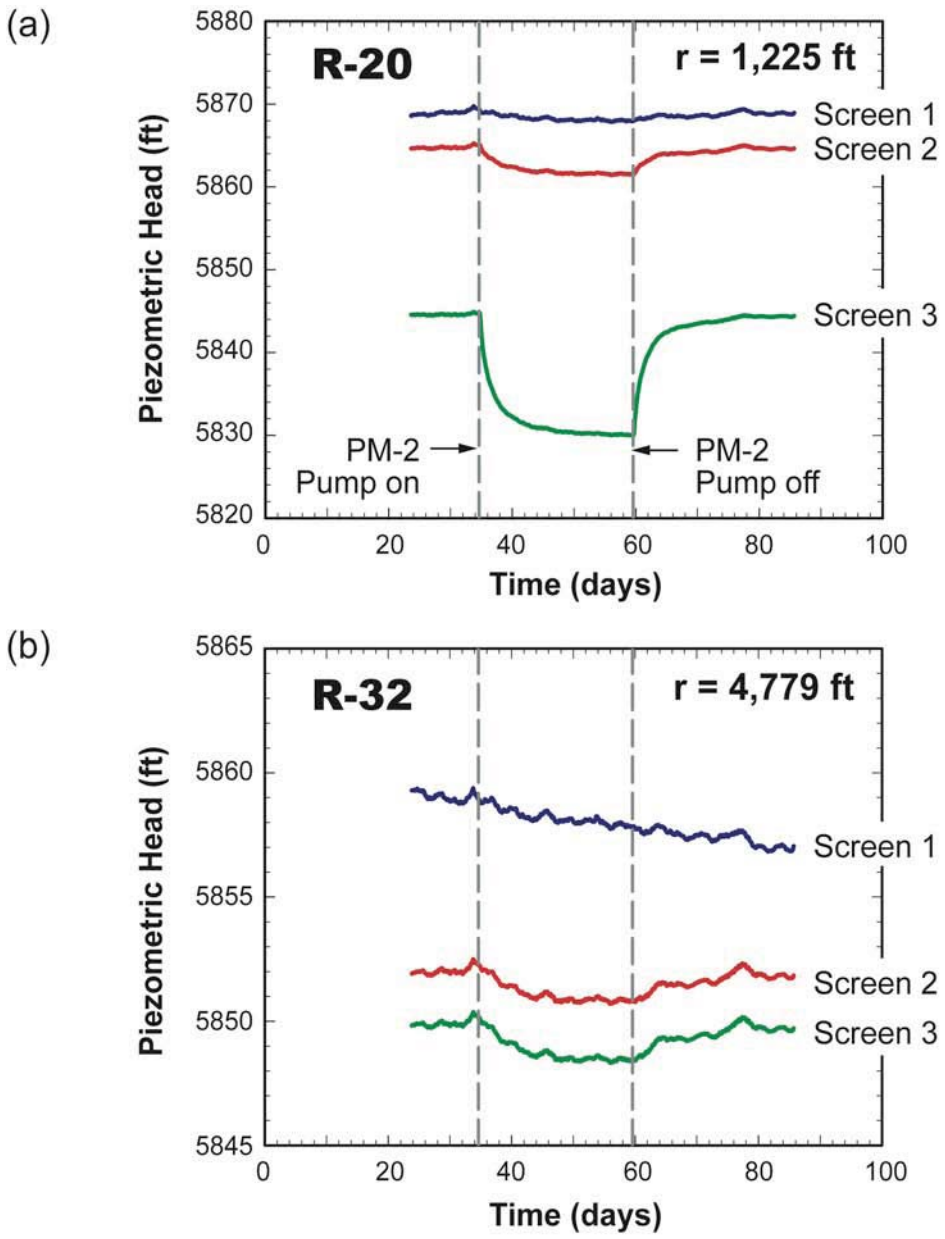

Figure 2-43. Drawdown at wells R-20 (a) and R-32 (b) in response to pumping at PM-2 (McLin, 2005).

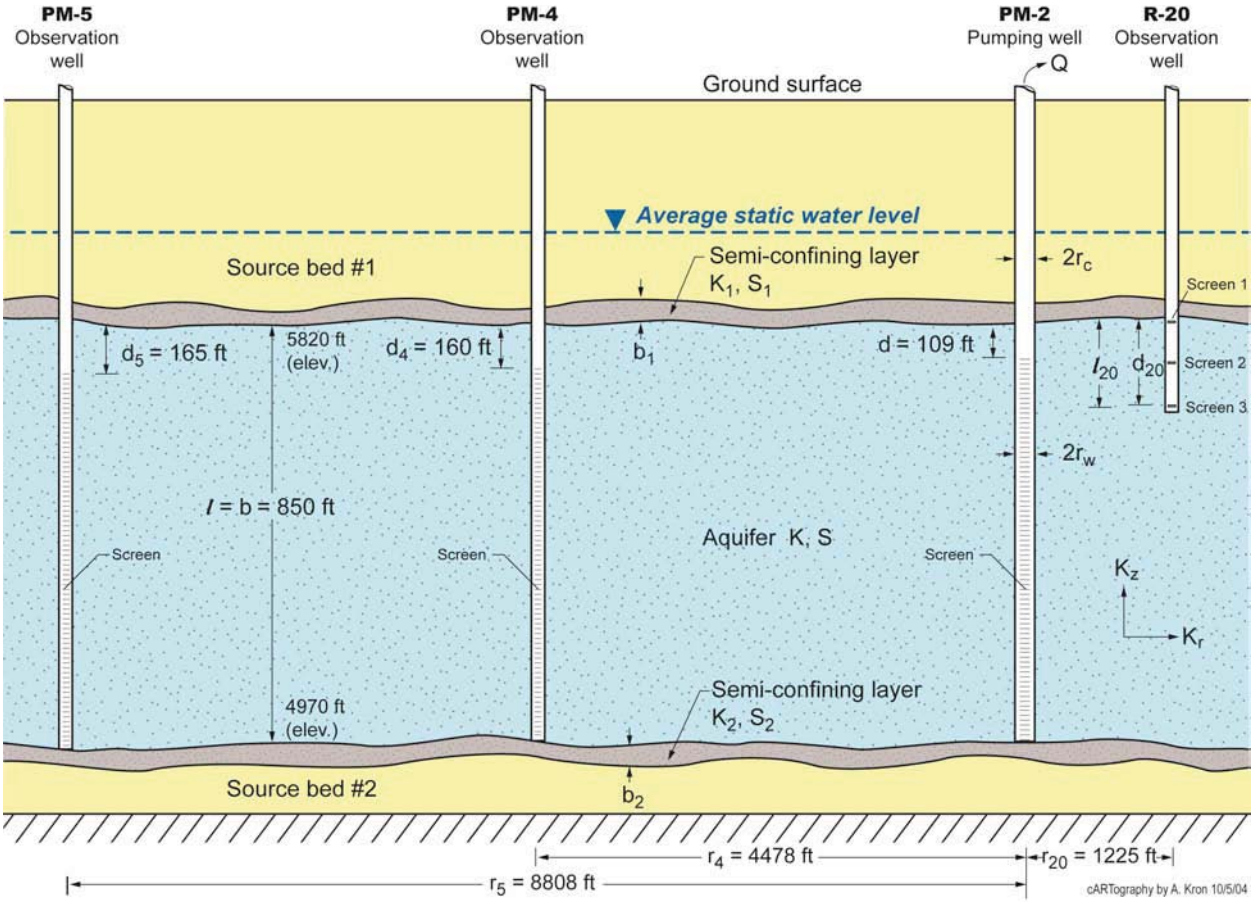

Figure 2-44. Idealized representation of the aquifer near PM-2 during the pumping test. A shallow system that includes the water table is separated from a deeper system by a semiconfining layer of low permeability (McLin, 2005).

The analysis of McLin (2005) suggested an aquifer that behaves as a confined system at early stages in the test, transitioning to a behavior characteristic of leaky-confined aquifer behavior when the long-term drawdown behavior is interpreted. Although the behavior of the pumping test has the signature of a leaky-confined aquifer, with a temporal stabilization of drawdown relative to a confined aquifer, other aquifer flow mechanisms can give rise to similar behavior. For example, either leakage from low-permeability aquitards within a confined aquifer or interception of the cone of depression with a recharge boundary is an alternative explanation. The pumping test illustrated the importance of conducting tests of long enough duration to discern the large-scale behavior of the aquifer at progressively larger scales. Additional tests at other municipal water supply wells are planned to probe the hydrodynamic conditions of the aquifer at different locations. By combining the results of several such tests, we should be able to sort out the various flow mechanisms, thereby uncovering a more detailed picture of flow paths and mechanisms in the aquifer.

2.8.6 Hydraulic Heads and Flow Directions

The principal reason for studying the regional aquifer in the Hydrogeologic Workplan activities is to determine the direction and rate of movement of water and contaminants. Historically, easterly/southeasterly flow directions in the regional aquifer have been proposed, based on data available to Purtymun and Johansen (1974) and Rogers et al. (1996b). Data collected as part of the Hydrogeologic Workplan confirm this result with a much larger number of wells than were available to earlier studies, particularly wells completed with short screens near the water table.

2.8.6.1 Water Level Map

The potentiometric surface for the regional aquifer is shown in Figure 2-24 (from LANL, 2005). Data used to construct this map are given in Table 2-10 for wells under water table conditions. In addition, data from wells under leaky-confined conditions in lower Los Alamos Canyon were included to augment the spatial coverage of the data because observations at the water table are not available at that location. The analysis of the data used to construct this and other maps of water levels and trends with time is discussed in detail in LANL (2005). The lateral component of gradients along the top of the aquifer beneath the plateau varies over one order of magnitude, from a low of 0.0026 (TW-3 to R-5) to a high of 0.04 (CDV-R-37 to CDV-R-15). Even higher gradients are evident west of R-25 (0.162; R-26 to R-25).

A simple conceptual model for these trends is that gradients are high to the west where significant recharge is occurring and gradients are low in the central plateau where lower recharge rates are occurring and higher permeability rocks are present (Purtymun, 1995). The general easterly-southeasterly flow direction suggested by these gradients is consistent with radiocarbon ages of water from deep wells beneath the Pajarito Plateau, which increase from west to east. Age estimates for groundwaters beneath the plateau range between about one to six thousand years, increasing to several tens of thousands of years near the Rio Grande (Rogers et al., 1996b). However, as will be discussed below, interpretation of these data is complicated by the fact that the flow patterns within the aquifer are complex, and mixing of fluids of different ages is likely. The presence of anthropogenic tritium in the regional aquifer demonstrates that mixed waters of vastly different ages are present in the aquifer.

2.8.6.2 Shallow and Deep Flow Paths

The nature of the measured head gradients suggests that flow in the shallow portion of the aquifer (less than 150 m) below the upper surface of the saturated zone is primarily easterly-southeasterly. The tendency for aquifer rocks to be strongly anisotropic will cause water to move in large part horizontally, despite the strong driving force of vertical head gradients. As described in the previous subsection, the degree to which the uppermost phreatic zone and the deeper, leaky-confined aquifer are hydrologically connected is not known with certainty. Nevertheless, hydrologic testing indicates that there is considerable resistance to vertical flow relative to horizontal flow; this phenomenon is likely to be widespread throughout the aquifer, but the magnitude of the anisotropy ratio at small scales probably varies considerably across the plateau. One interesting observation is that the amount of recharge estimated by Kwicklis et al. (2005) to occur in canyon bottoms on the plateau (77 kg/sec) is close to the total discharge from the springs of 85 kg/sec estimated by Purtymun (1966). This observation is consistent with a

compartmentalized aquifer with plateau recharge traveling laterally in the phreatic zone, partially isolated from deeper groundwater flow.

In general, the direction of flow in deeper portions of the aquifer (at depths greater than the deepest water supply wells) is unknown because of sparse data, and is likely to be different under pumping conditions than under pre-development conditions. Purtymun (1995) suggested that heads at deeper intervals of the aquifer also have a westerly gradient. It is conceivable that the predominant flow direction under natural gradient conditions could be different from what is found at shallower depths, but data to constrain the direction are insufficient. The conceptual model for the nature of flow discharging to the Rio Grande or flowing to the Albuquerque Basin to the south will likely influence the predicted flow direction deeper in the aquifer. A model with significant flow to the Albuquerque Basin (described in Section 2.8.3.3 as an alternate conceptual model) would lead to more southerly flow paths in the deep aquifer.

2.8.6.3 Influence of Water Supply Well Pumping

Despite evidence for compartmentalized flow with significant flow resistance between the shallower and deeper zones, it is likely that some downward movement of water and contaminants does occur due to pumping of water supply wells at depth. Occurrences of tritium and perchlorate in well O-1 show that flow paths between the shallow and deep aquifer water can exist during production. However, the extent of vertical transport is undoubtedly a function of the local permeability structure between the water table and the pumping interval in the water supply well, which may vary spatially across the plateau. Finally, pumping-induced upward movement of deeper water has been observed in the Los Alamos Canyon wellfield (Gallaher et al., 2004; Purtymun, 1977).

Although our understanding of the impact of water production on aquifer storage and discharge to the Rio Grande is incomplete, there is a clear trend of decreasing water levels over the time period of production from major wellfields on the plateau. Pumping rates increased from near zero in 1945 to 183 kg/sec in 1971 and have been relatively stable since then (171 kg/sec in 2001) (Koch et al., 2004); although year-to-year variability in pumping rates at individual wells has been large. Figure 2-45 (from LANL, 2005) shows the rate of water level decline in ft/yr estimated from long-term monitoring of water levels in wells on the plateau. Details of this map, constructed using a combination of test wells with a long (greater than 10 year) record and more recent characterization wells, are described in LANL (2005). The main features of the map are an area of high water-level decline rate (over 1 ft/yr) along Pueblo Canyon, which lies at the northern edge of data coverage, and an elongated zone of high decline rate (up to 0.8 ft/yr) that runs north to south, just east of and including PM-5, PM-4, and PM-2. This zone then extends east along Pajarito Canyon to R-23.

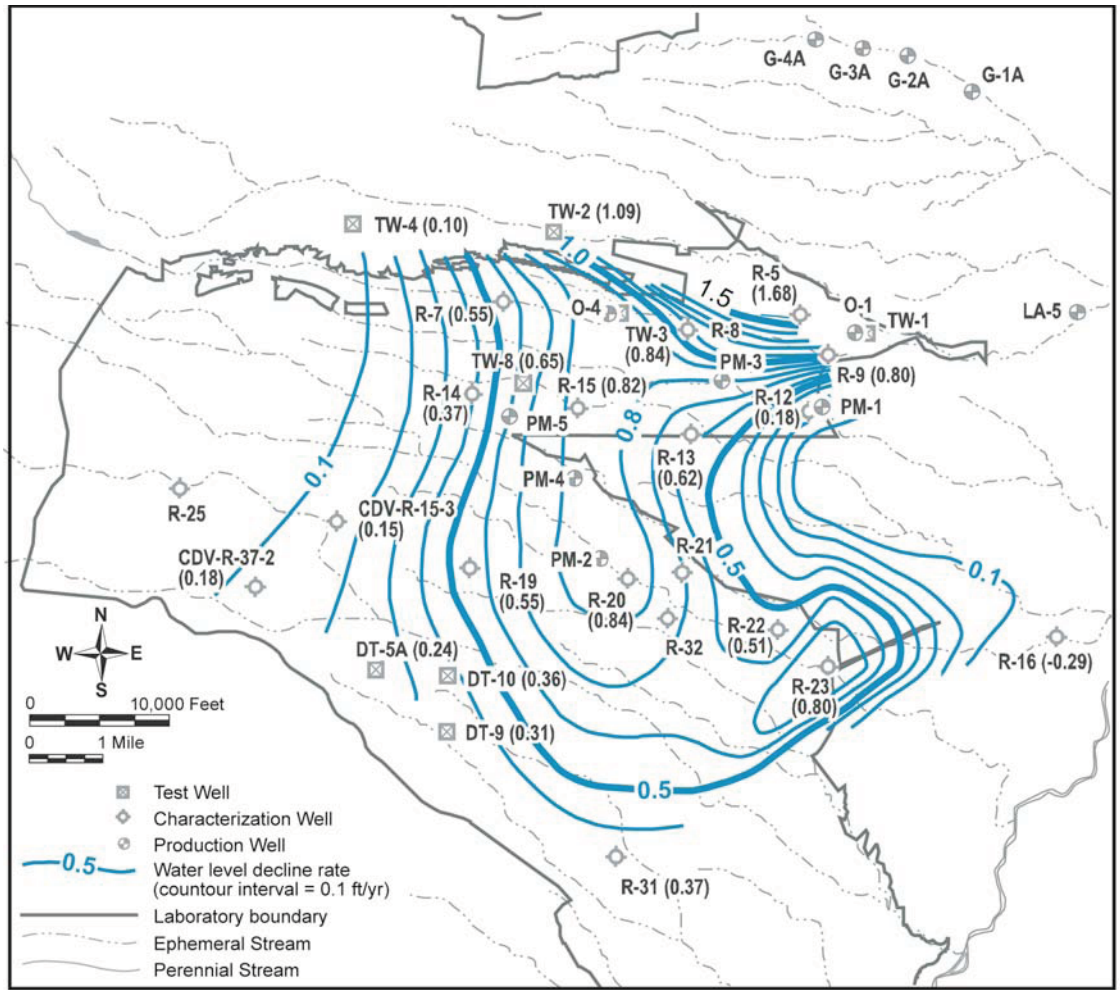

Figure 2-45. Annual water level decline due to municipal water supply well pumping (from LANL, 2005).

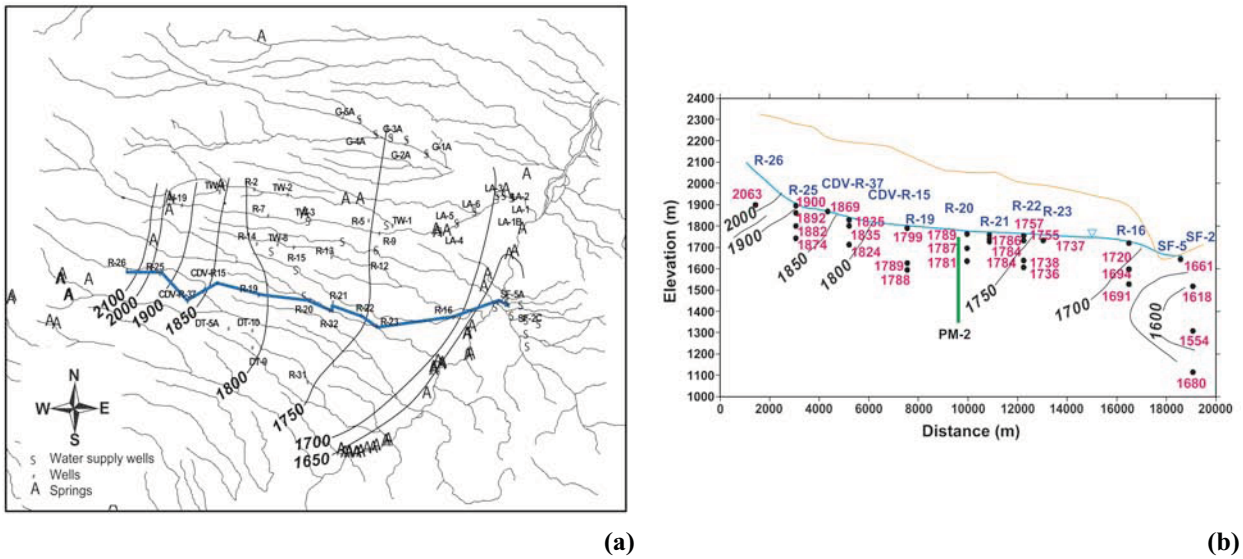
In the Los Alamos Canyon wellfield, after substantial water level declines when pumping initiated in the late 1940s, water levels rose and fell in response to inter-annual pumping variability. When the wells were retired in the late 1980s to early 1990s, water levels rapidly increased. Similarly, water levels in the Guaje wellfield decreased initially in response to pumping in the early 1950s and then stabilized until the 1970s; this was interpreted by Koch et al. (2004) to suggest that the aquifer had reached equilibrium. Water levels began to decline gradually again in the 1990s, perhaps due to pumping in nearby wellfields. Pumping in the Pajarito Mesa (PM) wellfield has produced less water level decline than pumping in the Guaje or Los Alamos Canyon wellfields, despite heavy usage. Nevertheless, water levels in PM-1 and PM-3, which have been pumped more consistently than other PM wells, have shown a long, steady decline. Test wells, which are much shallower than water supply wells, have also shown long, steady, declining water levels; before 1970 declines were very small (~1 m); since 1970 declines have increased to a total of ~5 m.

The impact of production on storage in the aquifer was estimated by Rogers et al. (1996b). They calculated storage depletion by estimating the volume of the combined cones of depression observed in all the wellfields on the plateau, assuming drainage under water table conditions, and by assuming uniform aquifer properties (porosity = 0.1). They concluded that the total storage loss has been approximately equal to total production in the time period 1949 – 1993, and thus perhaps that there has been no significant net recharge to the wellfields during this period. In contrast, McLin et al. (1996) suggested that significant recharge has occurred, since water levels have recovered in wells that were allowed to rest a period of several months or several years. Flow modeling is one approach to estimate the proportion of storage loss that has been replaced by recharge. Simulations suggest that flow beneath the Rio Grande (west to east) has been induced by production at the Buckman wellfield. Calculations show that this flux may have increased from zero (pre-1980) to approximately 45 kg/s at present, or ~20% of the total annual production at Buckman (Keating et al. 2003).

2.8.7 Aquifer Hydrodynamics

The hydrodynamics in various portions of the aquifer beneath the plateau is critical to determining the potential pathways of contaminant transport. There have been numerous theories proposed in the literature on the degree and extent of confined conditions of the plateau. This is not too surprising considering the extremely complex geologic structure of the plateau and the inherent limitations of short-term pumping tests. Based on limited data, Cushman (1965) concluded that the aquifer is under water-table conditions beneath the plateau, with the exception of the vicinity of the Rio Grande, where water-table conditions exist in shallow layers and confined conditions exist at depth. Purtymun (1974) suggested that water-table conditions exist on the western margin of the plateau and artesian conditions exist along the eastern edge and along the Rio Grande.



Drilling associated with the characterization program has confirmed existence of water-table conditions at many locations beneath the plateau. Table 2-10 shows the water levels in wells (or, for wells with multiple screens, in the uppermost screen below the water table) used to construct the water table map discussed in Section 2.8.6. Clearly, the characterization program has revealed the presence of unconfined conditions locally over most regions of the plateau, with the exception of locations near the Rio Grande, where confined conditions are generally observed.

Table 2-10.

Significant new information on the relationship of the shallow and deeper regional aquifer hydrodynamics has also been obtained. Potentiometric measurements at several new multiple-screened wells have revealed that decreasing head with depth is a pervasive feature of the aquifer. Head data (in meters) along a vertical cross-section in the southern portion of the plateau, where there are several wells with multiple completions, are presented in Figure 2-46. Decreasing head with depth has been observed in wells in the western portion of the Laboratory (see Figure 2-47 for well CdV-R-15-3) away from pumping well influence, but in a region where increased recharge is expected; near the Rio Grande (see Figure 2-48 for well R-16); in the central portion of the Laboratory (R-19, Figure 2-49); and in locations expected to be more strongly influenced by water supply well pumping (R-20, Figure 2-50). One counter example, well R-31 (Figure 2-51) located in the southern portion of the Laboratory away from municipal water supply wells and the region of expected high recharge, shows a very small (note the expanded scale of the y-axis compared to the other plots) decrease in head with screen depth between screens 2 and 3, but head increases with depth in the lower two screens 4 and 5.

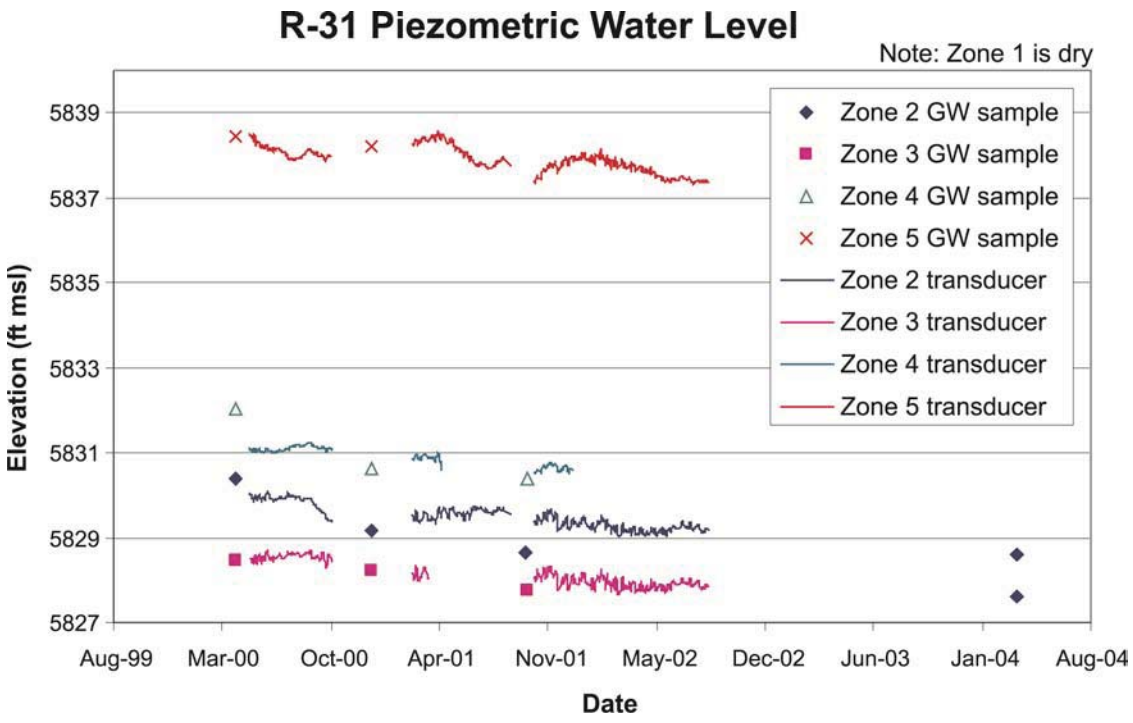

Figure 2-51. Piezometric water levels in different screens in well R-31.

There are several hydrologic mechanisms that can give rise to the observed data. First, note that in a region with a sloping water table, with recharge at high elevation and discharge at lower elevations, the theoretical result for a uniform medium is lower heads with depth, except close to the discharge zone. This explanation alone is consistent with the uppermost screens of R-31. At greater depths in R-31, the higher heads are perhaps due to a zone that is hydrologically separated from the upper zone, with higher head due to recharge to the west and deep, confined flow beneath the plateau. The reasons for the larger downward head drops in well CdV-R-15-3 (as well as other wells in the vicinity, such as R-25) are uncertain, but are probably due to a combination of high local and mountain front recharge, combined with an extremely complex hydrostratigraphic and structural condition in which poorly connected, compartmentalized flow zones are encountered with depth. The wells in the vicinity of water supply wells on the plateau are clearly influenced by water extraction. It is possible that relatively small head differences with depth before water withdrawal have grown substantially because of pumping. Although data on shallow and deep head declines due to long-term pumping are sparse, it is likely that drawdown at the elevation of pumping is highest, and a more muted drawdown exists at the water table. Finally, for R-16, the lower head with depth is probably caused by pumping at the Buckman wellfield.

The critical element that appears to be necessary to explain the observations from both pumping tests and information from multiple-screened wells is the presence of different hydrodynamic conditions at depth than are present at the top of the regional aquifer. The observations (unconfined conditions and a muted response to pumping at depth) suggest a phreatic zone under water-table conditions that is weakly connected hydrologically to a deeper zone that behaves as a leaky-confined aquifer.

The nature of the aquifer heterogeneities giving rise to this compartmentalized system remains an open question. Two conceptual models appear to be possible. One is that the strongly anisotropic characteristic of the aquifer, which limits vertical movement of groundwater at virtually all depths within the Puye Formation and Santa Fe Group, produces the observed trends with depth. Cushman (1965) noted that this aquifer characteristic can cause an unconfined aquifer to appear confined in a short-term pumping test. This explanation is consistent with the observation of McLin (2005) described in Section 2.8.5 of a hydrograph that transitions from confined to leaky-confined behavior at later times. This conceptual model is implemented in the numerical models of McAda and Wasiolek (1988) and Hearne (1980). The McAda and Wasiolek (1988) model places the majority of water supply wells in the basin within the upper 600-ft-thick unconfined layer of the model.

Another conceptual model is that a laterally extensive low permeability zone exists within the aquifer separating the shallow phreatic zone from a deeper confined aquifer. This is the conceptualization depicted in Figure 2-44. A single, laterally extensive zone of low permeability has not yet been identified in boreholes on the plateau. This fact, combined with observations indicating vertical resistance at all elevations in basalts, the Puye Formation, and the Santa Fe Group, strongly favor the former conceptual model. Either model would be expected to give rise to lateral transport of contaminants reaching the water table, especially at locations relatively unaffected by municipal water well pumping. The anisotropic model would allow for vertical

contaminant pathways to water supply wells in locations where continuous high-permeability pathways are present.

2.8.8 Velocities and Travel Times

Transport velocities and travel times through the regional aquifer are poorly understood, because of the lack of tracer tests and in-situ measurements of effective porosity. Data concerning the spatial distribution of anthropogenic contaminants in the regional aquifer have been difficult to use to constrain regional aquifer travel times because of the exceptionally thick and complex vadose zone, which makes it impossible to define the location and timing of contaminant entry to the regional aquifer. Transport over significant distances in the alluvial aquifers is known to occur, and complex vadose zone lateral pathways are also possible, though they have not been directly observed, except for the shallow subsurface pathways identified in the mountain front portion of the plateau (See Section 2.6.2.1). Despite these limitations, we note that no evidence of larger-scale migration of contaminant plumes has been observed, although the presence of anthropogenic chemicals at low levels in springs discharging to the Rio Grande at White Rock Canyon has been suggested by some to be due to regional aquifer transport (Section 3.2). Lack of evidence of migrating plumes may indicate that they travel too slowly to be observed over the relatively short period of study, or that sampling locations are not present in the right locations in sufficient density to track a migrating plume.

In principle, isotopic data can constrain possible transport velocities. These data clearly demonstrate that some waters beneath the plateau and discharging to the Rio Grande are thousands of years old, similar to ages of groundwaters measured in the Albuquerque Basin to the south (Plummer et al., 2004). Tritium data, described in Section 2.8.3, clearly demonstrate that young waters are present as well. These young and old waters may co-mingle at numerous locations within the aquifer including the discharge zone at the Rio Grande.

Therefore, there is no single answer to the question: How old is the groundwater? Mixing between older and younger waters is the norm for the waters sampled from the regional aquifer. Figure 2-52 illustrates that in many instances, both younger and older components are present. Tritium measurements at wells tapping the top of the regional aquifer near Los Alamos Canyon and Mortandad Canyon (among others), as well as isolated observations that include some of the springs discharging at White Rock Canyon, indicate a component of the water is young (less than 60 years old). Reconciling these observations with age estimates of several thousand years based on C-14 requires a model in which fluids of vastly different ages mix, yielding disparate age estimates from the different groundwater tracers.

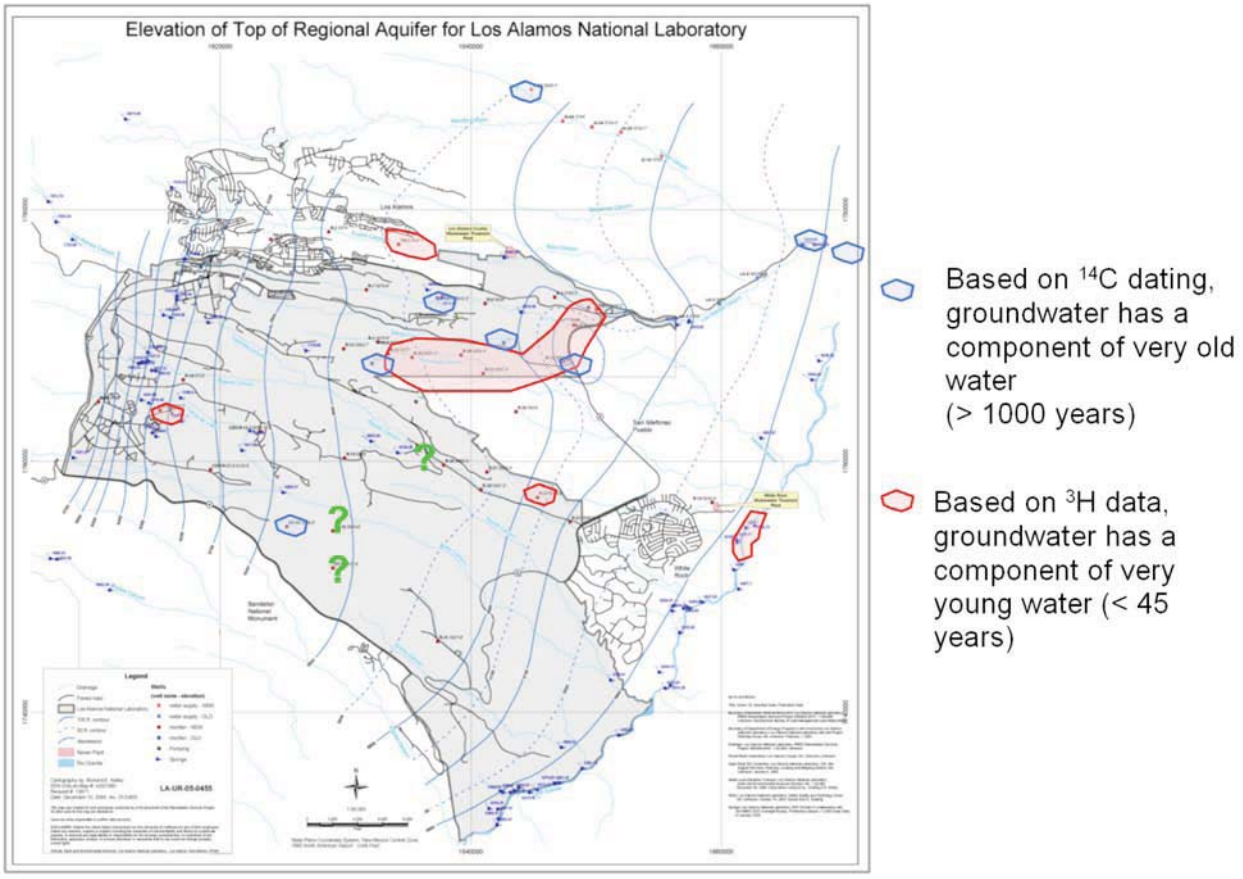

Figure 2-52. Diagram of the locations of "young" and "old" water at different locations. The figure shows that waters with different apparent ages, based on different geochemical indicators, can co-exist at the same location.

The model prediction of transport velocity and ultimate point of discharge of a contaminant in the regional aquifer is intimately tied to, even controlled by, the conceptual model used to develop the numerical model. If the picture emerging from the data described above of a compartmentalized aquifer is valid, then contaminants would travel laterally in the phreatic zone and arrive at springs discharging at the Rio Grande. These flow paths would be predominantly within the Puye Formation and the Cerros del Rio basalts, the geologic units commonly present at the water table of the regional aquifer (Figure 2-10). Travel times through these rocks might be expected to be relatively short. For example, taking the hydraulic conductivity of 1 m/d, a gradient of 0.02, and a porosity of 0.1, the computed velocity of a contaminant moving with the water (with no adsorption to the rock) is about 70 m/yr. Travel times on the order of 100 years would therefore be predicted to the springs from the most easterly zones of contaminated waters in the alluvial aquifers on LANL property.

The role of supply-well pumping in altering these directions and points of discharge is a function of the conceptual model and the water usage scenario chosen for examination. Section 4.2.12. presents a capture zone analysis suggesting that contaminants reaching the regional aquifer beneath canyons on the plateau will be largely captured by the PM wells. Anisotropic conditions in the regional aquifer that tend to keep transport pathways shallow are overcome by induced

downward gradients, and contaminants are drawn to the depths of the screens of the water supply wells, where they are captured. Implicit in these results is the conceptualization of discrete pathways leading to downward transport, perhaps through tortuous "windows" of high-permeability rock in between discontinuous low-permeability layers. A more continuous low-permeability zone between the contaminant residing at the water table and the water supply well would create two disconnected zones at the scale of a contaminant plume. Under this scenario, contaminants would be isolated to the phreatic zone and travel to a down-gradient supply well or the Rio Grande, despite pumping near the contaminant source.

Another important consideration is that steady-state capture-zone results require the assumption of constant pumping for a long enough time for a water particle to arrive at the well. This water usage scenario maximizes the induced downward gradient, exaggerating the downward gradients and leading to flow paths in which capture by the water supply wells is favored over lateral transport at shallow depths. If transport velocities are low enough, water supply wells are likely to be taken out of service before this theoretical arrival at the well would occur. In this case, the actual transport problem is inherently transient, and predictions are intimately tied to the actual water withdrawal scenario. In summary, these complexities render the predictions model- and scenario-dependent. Interpretations based on such models must keep this fact in mind. In the future, a broader range of water-usage scenarios and transient capture zone analyses should be used to fully explore these alternatives.

3.0 GROUNDWATER GEOCHEMISTRY, CONTAMINANT DISTRIBUTIONS, AND IMPLICATIONS FOR FLOW AND TRANSPORT

It is important to understand geochemical processes and the natural water quality beneath the Pajarito Plateau, so that anthropogenic perturbations to the natural system can be identified and quantified. The natural geochemistry of groundwater is the result of physiochemical interactions between air, water, soil, biota, and aquifer material. Geochemical processes are influenced by several factors, including the composition of the groundwater, groundwater temperature, microbial populations, the mineralogical composition of the aquifer material(s), and the length of time the water is in contact with aquifer material(s). Section 3.1 describes the conceptual model of geochemical processes and reactions for the Pajarito Plateau and surrounding area. It also describes the "background" water chemistry, that is, the water chemistry not affected by Laboratory activities.

Imprinted on the natural variations in chemistry is the presence of contaminants historically released since the early 1940s when Laboratory operations commenced. While most of the contaminants are at concentrations largely below regulatory standards, they demonstrate the presence of pathways for groundwater flow and contaminant transport from the surface to deeper groundwater. The impacts to groundwater at the Laboratory have occurred mainly where effluent discharges have caused increased infiltration of water. The depth to which chemical constituents move in the subsurface is determined partly by their chemical behavior: non-reactive constituents move readily with groundwater, while reactive or adsorbing constituents move a shorter distance.

In most cases where effluent sources have been eliminated, groundwater concentrations of non-reactive discharged contaminants have decreased far below past levels (e.g., RDX, nitrate, tritium, and perchlorate) in alluvial groundwater. These mobile contaminants readily move through the subsurface and are detected within perched intermediate zones and at the regional water table beneath several canyons, including Pueblo Canyon, Los Alamos Canyon, Sandia Canyon, Mortandad Canyon, and Cañon de Valle (HE in Cañon de Valle is an exception to this). In the case of reactive or adsorbing chemicals, the concentrations remain elevated significantly above background levels after elimination of discharges or other contaminant source terms (e.g., excavation and removal of contaminated sediments). These include constituents such as strontium-90 and the actinides (americium-241, plutonium-238, and plutonium-239,-240). A discussion of observed contaminant distributions within alluvial and perched intermediate zones and the regional aquifer is provided in Section 3.2. Many of the characterization wells and their chemical data are not included because characterization sampling conducted as part of the Hydrogeologic Workplan is not complete.

3.1 Geochemical Conceptual Model

A geochemical conceptual model that describes the geochemical environment beneath the Pajarito Plateau combines knowledge of geochemical processes with observations of water chemistry at sampling locations and mineralogy of aquifer materials. The components that contribute to the geochemical conceptual model include

- natural chemical compositions of groundwater,

- residence time,
- reactive minerals controlling groundwater composition and solute mobility,
- adsorption and precipitation reactions,
- redox conditions controlling solubility, and
- chemical speciation.

The following subsections discuss these conceptual model components and describe the observations and data that are the basis of each component.

3.1.1 Natural Chemical Composition of Groundwater

Groundwater occurs in three hydrostratigraphic settings beneath the Pajarito Plateau, which include the alluvium, perched intermediate zones (Bandelier Tuff, Cerros del Rio basalt, and the Puye Formation), and the regional aquifer (Puye Formation, Cerros del Rio basalt, older basalts, and the Santa Fe Group). As a result of geochemical processes, the natural composition of groundwater in the three hydrostratigraphic settings varies along flow paths from recharge areas in the Sierra de los Valles, west of the Laboratory, to the discharge areas along the Rio Grande to the east. Recharge also occurs along canyon reaches that contain saturated alluvium.

A hydrochemical investigation was conducted from 1997 to 2000 to define the background chemical composition of groundwater beneath the Pajarito Plateau. Based on the data and information compiled, the statistical properties of natural (background) distributions of stable isotopes (δD, $\delta^{15}N$, and $\delta^{18}O$), tritium, and major and trace solutes in groundwater were established. A complete description of the background study is available in LANL (2005a).

Natural groundwater (alluvial, intermediate, and regional aquifer) ranges from calcium-sodium bicarbonate composition within the Sierra de los Valles to a sodium-calcium bicarbonate composition east and northeast of the Laboratory. Sodium bicarbonate groundwater occurs within the regional aquifer in lower Los Alamos Canyon and at several White Rock Canyon springs near Otowi Bridge (Blake et al. 1995; LANL, 2001a; LANL, 2002; LANL, 2004b). Figure 3-1 shows average background concentrations of specific conductance, major cations and anions, silica, tritium, and several trace elements including barium and uranium analyzed during six sampling rounds (LANL 2005a).

Concentrations of trace elements increase from alluvial groundwater to perched intermediate zones to the regional aquifer. They also increase from west to east within the regional aquifer due to increasing solute residence times and water/rock interactions, including recipitation/dissolution and adsorption/desorption reactions. The highest natural solute concentrations are associated with older groundwater within the regional aquifer. Concentrations of dissolved bicarbonate, sodium, calcium, and uranium increase from west to east. The following subsections discuss the evolution of natural groundwater chemistry from the recharge zone, along the flow paths, and out to the discharge zone.

3.1.1.1 Geochemistry of the Recharge Zone

Groundwater generally has the lowest total dissolved solids (TDS) in the recharge area and increases in TDS along flow paths (Figure 3-1, where TDS is approximated by specific conductance). The Sierra de los Valles provides most of the recharge to groundwater beneath the Pajarito Plateau, based on distributions of stable isotopes, including δD and $\delta^{18}O$ ratios (Figure 3-2). This interpretation was presented in Section 2.8.3.1.1. Recharge water derived from precipitation near the Sierra de los Valles contains natural tritium (19 to 71 pCi/L), which decays to less than 3 pCi/L along groundwater flow paths within non-contaminated perched intermediate zones and the regional aquifer beneath the central and eastern parts of the Laboratory (Figure 3-1).

3.1.1.2 Aqueous Geochemistry along the Flow Path

This subsection evaluates or describes solutes or dissolved species occurring along groundwater flow paths, which show variation among the three types of saturated zones. Variation in solute concentration results from the mixing of groundwaters, mineral precipitation (solute sink), mineral dissolution (solute source), and adsorption/desorption reactions. Natural groundwater quality in the regional aquifer beneath the Pajarito Plateau is excellent and, with the exception of arsenic in Guaje Canyon groundwater, does not exceed federal and state drinking water standards.

The occurrence of reactive minerals within aquifer material controls the composition of groundwater chemistry along flow pathways. Calcium, sodium, and bicarbonate are the dominant major ion solutes in natural groundwater beneath the Pajarito Plateau and surrounding areas. Bicarbonate is the dominant anion in groundwater at Los Alamos (LANL 2005a). This solute increases in background concentrations from shallow alluvial groundwater to the regional aquifer (Figure 3-3). Bicarbonate forms complexes with several trace metals, which has a direct influence on the metal's mobility or transport in the subsurface. Low concentrations of natural bicarbonate and calcium within the alluvium and perched intermediate zones within the Bandelier Tuff and the Puye Formation are insufficient to precipitate calcium carbonate (calcite) (Figure 3-4). Calcite is not typically observed within these saturated zones under natural conditions. In contrast occurrences of calcite within the Santa Fe Group basalt and sediments are reflective of higher concentrations of both calcium and bicarbonate.

Silica is the next most abundant solute found in surface water and groundwater within the Los Alamos area (Figure 3-1) because of hydrolysis reactions taking place between soluble silica volcanic glass and water. All groundwater sampled as part of the background investigation (LANL 2005) are oversaturated with respect to quartz, which is the most stable mineral of the silica phases (Lindsay 1979). Dissolved silica concentrations, however, are not controlled by quartz because this mineral is less reactive than volcanic and sedimentary glass found within the different hydrostratigraphic units. Groundwater within the three groundwater zones is calculated to be in equilibrium with silica glass. In some instances, dissolved silica can be used as a tracer to evaluate groundwater flow from the silica-rich (pumice-rich) Puye Formation to the underlying Santa Fe Group basalt encountered at wells R-9 and R-12. Groundwater flowing through the Bandelier Tuff (well LAOI(A)-1.1) and some sections of the pumiceous-rich Puye

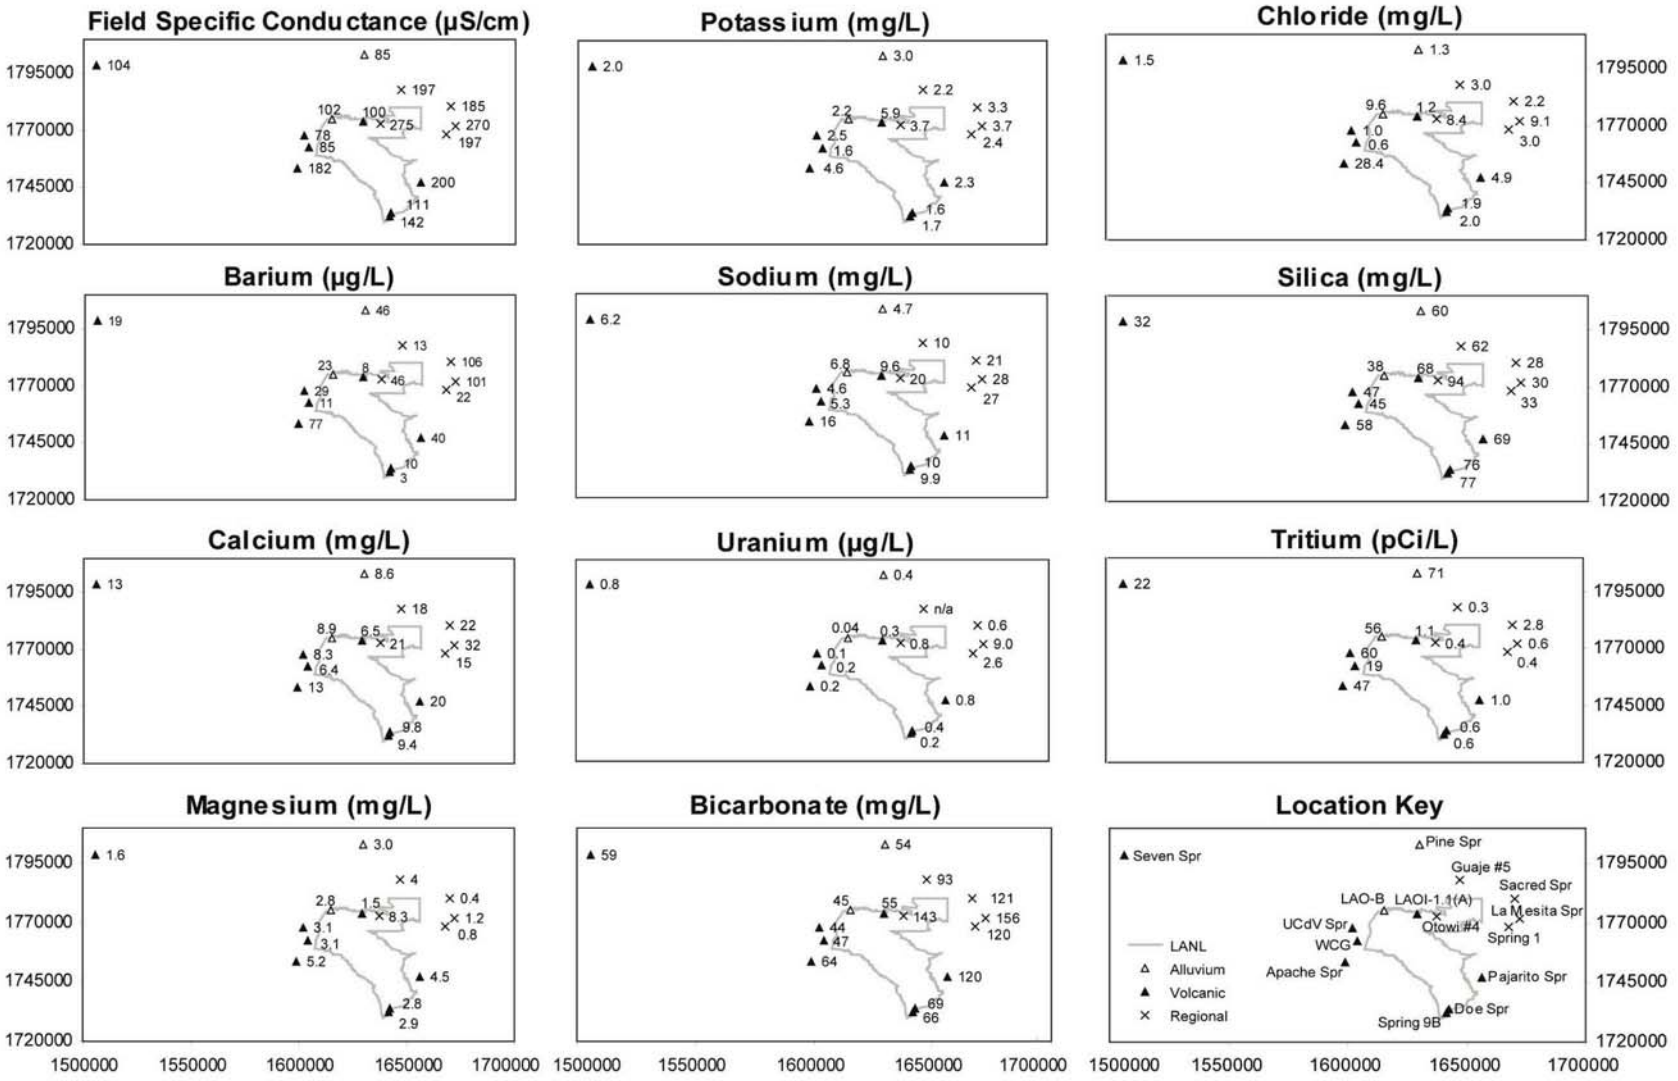

Figure 3-1. Average spatial distributions (n = 6) for key analytes in LANL background wells and springs (LANL, 2005a).

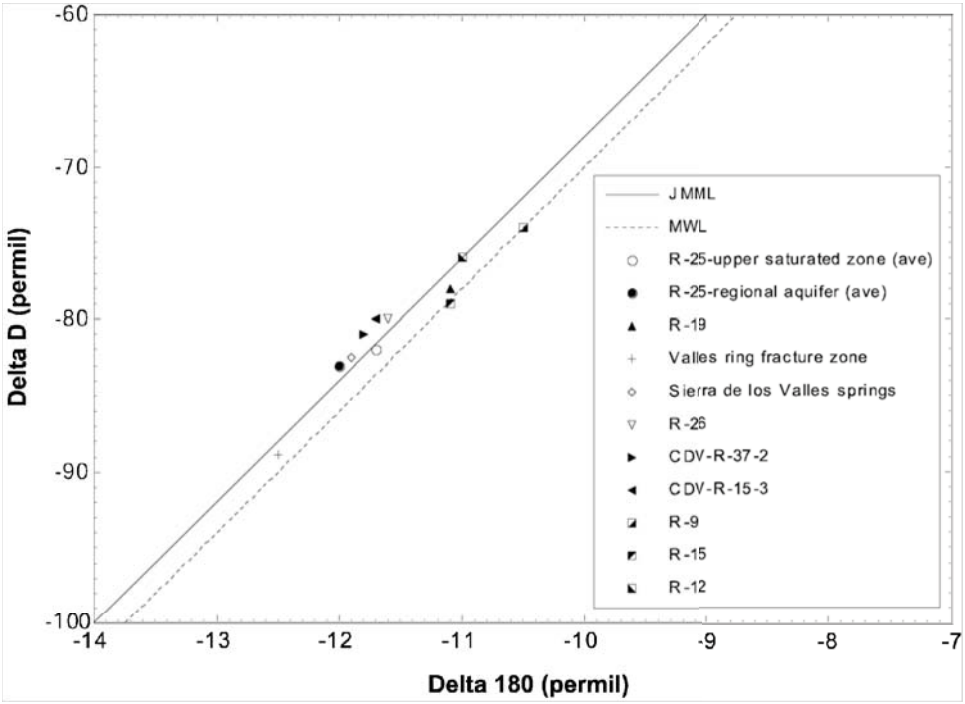

Figure 3-2. Stable isotope results for wells R-9, R-12, R-15, R-19, R-25, R-26, CdV-R-15-3, and CdV-R-37-2, and for other springs in the Jemez Mountains. (The upper line is the Jemez Mountains meteoric line and the lower is the mean worldwide meteoric line.)

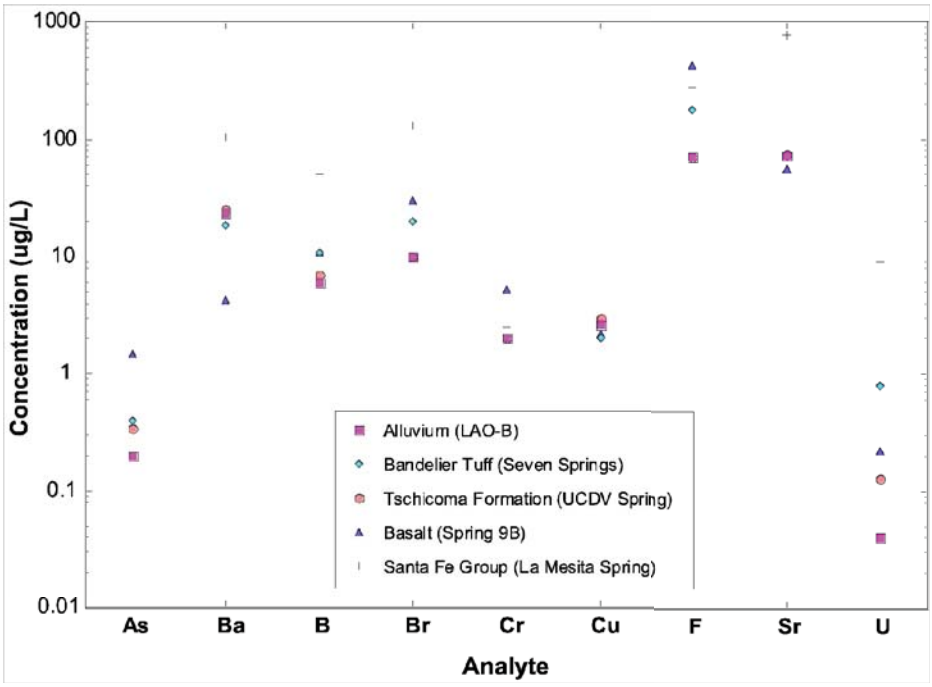

Figure 3-3. Average dissolved concentrations of selected natural trace elements in a represenative well or spring within alluvial and perched intermediate groundwater and the regional aquifer. Note: Average of six rounds.

Formation (wells R-7 and R-15) is characterized by higher dissolved silica concentrations than groundwater flowing through the Cerros del Rio basalt (well R-9i and Spring 9-B) (Figure 3-4). This contrast is attributable to the fact that the volcanic glass within the basalt is both less abundant and less reactive than the ubiquitous glass within the Otowi Member of the Bandelier Tuff and pumiceous-rich Puye Formation.

Figure 3-3 shows average dissolved concentrations of several natural trace elements within alluvial and perched intermediate groundwater and the regional aquifer. Average concentrations of natural arsenic, chromium, and fluoride were the highest within the Cerros del Rio basalt (Spring 9B). Variations in groundwater trace element concentrations depend on solute residence time, speciation, and extent of water-rock interactions. Many trace elements show considerable variations, even in young recharge water. For example, average concentrations of barium, boron, bromide, strontium, and uranium are the highest within the regional aquifer in the Santa Fe Group at La Mesita Spring. Average concentrations of dissolved natural uranium were 9.1 μg/L at La Mesita Spring, which is 300 times greater than that observed at well LAO-B in alluvium (Figure 3-3).

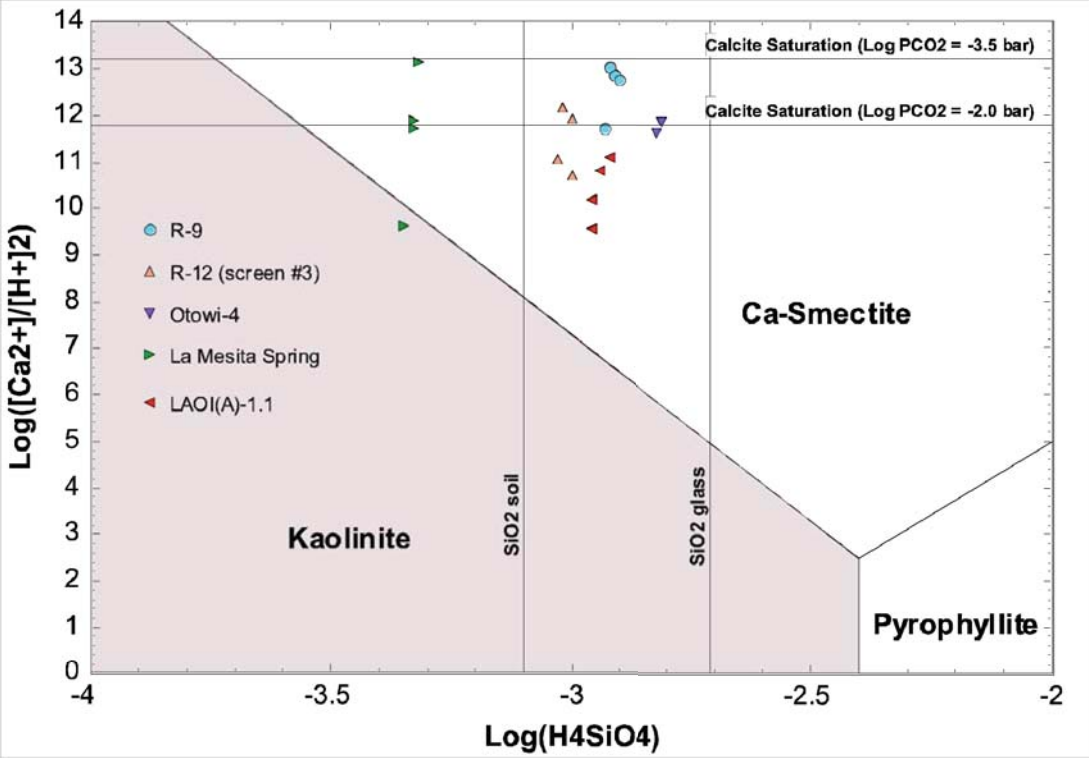

Figure 3-4. Activity diagram of log activity [H_4SiO_4] versus log activity $Ca^{2+}/[H^+]^2$ at 25°C for wells Otowi-4, R-9, R-12 (screen #3), and LAOI(A)-1.1 and La Mesita Spring.
Note: These were selected because of observed smectite in x-ray diffraction of core and cuttings.

Naturally occurring solid organic matter containing carbon, oxygen, nitrogen, and hydrogen is an important component of alluvial sediments within and surrounding the Laboratory. Dissolved organic carbon (DOC) is derived from leaching of solid organic matter and concentrations of DOC are typically less than 2 mg carbon (C)/L within perched intermediate zones and the regional aquifer. Higher concentrations of DOC (up to 20 mg C/L) are found in soil, surface water, and alluvial groundwater within the upper reaches of Los Alamos Canyon where runoff through grasslands and forests takes place. The DOC contains dissociated carboxylic acids that are stable as anions above pH 4.5 (Thurman, 1985). The anions are mobile in the groundwater. Dissolved organic carbon mainly occurs in the forms of humic and fulvic acids (Vilks and Bachinski, 1996). These acids occur as anions and can complex with calcium and magnesium, which can influence precipitation reactions involving calcite.

Leaching of ash produced from the Cerro Grande fire in May 2000 resulted in the generation of elevated concentrations of total organic carbon (TOC), consisting of both DOC and suspended organic carbon (SOC). Shortly after the Cerro Grande fire, increased concentrations of TOC were observed in surface water and alluvial groundwater within Pueblo Canyon, Los Alamos Canyon, Pajarito Canyon, and other watersheds. Since 2002, concentrations of TOC have decreased in surface water, but remain elevated in alluvial and perched-intermediate groundwater. Total organic carbon provides an excellent tracer for tracking movement of recent water (post Cerro Grande fire) in the subsurface. For example, concentrations of TOC have exceeded 300 mg C/L in perched zones within the Cerros del Rio basalt at the Los Alamos Canyon weir (Stone et al., 2004).

3.1.1.3 Geochemistry of the Discharge Zone

Groundwater chemistry within discharge zones can significantly differ from that characteristic of recharge zones. Total dissolved solids generally increase along groundwater flow paths. Specific conductance provides an indirect measurement of TDS and both parameters increase from west to east along groundwater flow paths. For example, groundwater within the Sierra de los Valles contains specific conductance values typically less than 100 μS/cm (Figure 3-1). Springs discharging within White Rock Canyon, however, have specific conductance greater than 100 μS/cm. Concentrations of sodium also increase relative to calcium and magnesium at selected White Rock Canyon springs. This change in major cation chemistry most likely results from cation exchange processes with reactive minerals along flow paths, including smectite, kaolinite, and volcanic glass (discussed in Section 3.1.3).

Groundwater within a discharge zone, at the end of groundwater flow paths, generally has the highest mineral or solute content and also represents the oldest water, provided that mixing with younger groundwater has not taken place. The main groundwater discharge zone for the Sierra de los Valles and the Sangre de Cristo Mountains occurs as springs and gaining reaches along the Rio Grande. Older groundwater within the regional aquifer tends to have higher concentrations of trace elements due to a combination of mineral dissolution and desorption processes. Many trace elements, including arsenic(III, V) and uranium(VI), form anions and tend to desorb from mineral surfaces under basic pH conditions (Langmuir, 1997). Dissolved concentrations of major cations and anions, arsenic, uranium, and other trace elements are higher in groundwater east of the Rio Grande based on water quality/geochemical data collected by the New Mexico

Environment Department (NMED) and most recently by LANL. Based on water samples brought in to the Pojoaque water fair in 2004, concentrations of natural uranium in groundwater are generally in the range from up to 0.2 ppm along the Rio Grande and eastward toward the Sangre de Cristo Mountains. In contrast, uranium concentrations in the regional aquifer beneath the Pajarito Plateau rarely exceed 0.1 ppm.

In the discharge zone, as well as along flow paths, tritium is an excellent tracer that can be used to qualitatively date or bound the age of groundwater less than 61 years old, with a few exceptions. Background springs discharging within White Rock Canyon typically have tritium concentrations less than 1 pCi/L, indicating that groundwater is greater than 61 years old. This pre-dates historic discharges associated with the Laboratory and atmospheric fallout that may provide sources of recharge. These springs are characterized by groundwater flow paths that are of variable lengths and differing groundwater residence times.

3.1.2 Residence Times

Residence times of groundwater and chemical solutes increase both with depth and from west to east across the Pajarito Plateau within each groundwater zone. Groundwater flow paths within the regional aquifer generally are from west to east based on water level measurements. Accordingly, the concentrations of natural major ions and trace elements increase with distance along flow paths.

In the Sierra de los Valles, a known recharge area west of the Laboratory, a component of groundwater is less than 61 years old, based on measurable activities of tritium observed in springs. Movement of groundwater through fractured volcanic rock within the Sierra de los Valles is rapid in most cases (Water Canyon Gallery, Apache Spring, upper Cañon de Valle Spring, and Pine Spring). With a few exceptions, most springs in the discharge zone in White Rock Canyon, however, do not contain tritium, and the age of groundwater probably ranges between 3,000 and 10,000 years and possibly even older (Rogers et al. 1996b).

The oldest groundwater residence times within the regional aquifer are on the order of several to tens of thousands of years, based on carbon-14 dating (Rogers et al, 1996b). The carbon-14 dates provide a reasonable estimate of the maximum age of groundwater within the regional aquifer, provided that mixing with more recent water or older water with lower alkalinity has not taken place. Groundwater within the regional aquifer becomes progressively older from west to east (Rogers et al, 1996b). Presence of tritium near the water table and within the regional aquifer beneath the Laboratory, however, confirms that a much younger component of groundwater is present in the regional aquifer. Small concentrations of anthropogenic tritium (less than 100 pCi/L) at some locations are suggestive of mixing of a majority of old water with a component of young water at the regional water table. Mixing ratios using chloride or bromide are needed as additional information to more precisely determine fractions of young and old groundwater.

3.1.3 Reactive Minerals Controlling Groundwater Composition and Solute Mobility

Because there are variations in pH, temperature, and major ion and trace element chemistry within shallow and deep saturated zones, different reactive minerals and amorphous solids precipitate or dissolve. In some instances, they control the major ion composition of groundwater. Some of these phases, including hydrous ferric oxide, manganese (oxy)hydroxide, smectite, calcite, and zeolites, have a high adsorptive capacity for trace elements including chromium, lead, strontium, and thorium, and radionuclides including americium-241, cesium-137, and plutonium-238, -239, -240. Reactive minerals and amorphous solids approach equilibrium with groundwater when the residence time exceeds the reaction half time (amount of time required for 50% of reactant A to form product B assuming there is no B initially present). This condition is usually met within perched intermediate zones and the regional aquifer based on observed mineralogy, because hydrous ferric oxide is present in all the groundwater zones.

Calcite and smectite are two important minerals that have been observed in core samples collected from several R wells. The stability of reactive phases, including $CaCO_3$ (calcite) and calcium smectite, can be evaluated by considering concentrations of major dissolved ions, chemical composition of minerals, and equilibrium concepts. Figure 3-4 is a log activity diagram showing the stability of several minerals including kaolinite, pyrophyllite, silica soil, silica glass, and calcium smectite. Groundwater samples collected from selected wells R-9, Otowi-4, R-12 (screen #3), and LAOI(A)-1.1 and La Mesita Spring are also plotted on the figure. Important points from this figure are as follows:

- Most groundwater is oversaturated with respect to calcium smectite, as the groundwater samples plot within that stability field.
- One sample collected from La Mesita Spring plots within the stability field for kaolinite due to a lower pH measurement.
- Groundwater is oversaturated with respect to SiO_2 soil (amorphous silica) and undersaturated with SiO_2 glass, which suggests that some of the silica could be formed from pedogenic (soil-forming) processes.
- La Mesita Spring (representative of young recharge water) is undersaturated with respect to silica soil and silica glass and has lower concentrations of silica relative to those measured in groundwater samples collected at wells R-9, Otowi-4, R-12, and LAOI(A)-1.1.

Under equilibrium conditions, calcite controls dissolved concentrations of calcium and bicarbonate within the regional aquifer. Beneath the western and central portions of the Laboratory, however, calcite is relatively rare in most of the lithologies characterized at the regional aquifer water table (Figure 2-10) except for the pre-Puye Formation Santa Fe Group sediments. These sediments have variable amounts of dispersed calcite cement (0-20 wt%). There is also a zone of post-depositional alteration centered in the northeastern portion of the Laboratory where calcite alteration is common in the Puye fanglomerate and the pumiceous sediments. Calcite precipitation is observed in Santa Fe Group sediments near the Rio Grande.

As groundwater flows through perched intermediate zones and the regional aquifer, chemical and mineralogical compositions of reactive phases, including silica glass, change over time. For example, silica glass is the most soluble component of the aquifer material (Puye Formation and unassigned pumiceous unit) and reacts with groundwater to form clay minerals, such as kaolinite and smectite. These alteration phases have been observed at wells R-5, R-8A, R-9, and R-12. Calcium-sodium smectite has been observed in core and cutting samples collected from R-9 (Broxton et al., 2001a). Smectite has also been observed in rock samples collected from Santa Fe Group sediments in lower Los Alamos Canyon (Vaniman, unpublished data). The presence of smectite enhances natural attenuation of anthropogenic metals stable as cations, including strontium and barium, because this phase increases the adsorption capacity of the aquifer material under circumneutral pH conditions (discussed in more detail in Section 3.1.4).

The saturation index (SI) is an indicator of whether a mineral is likely to precipitate or dissolve under particular groundwater conditions. The SI is defined as the $\log_{10}$(activity product/solubility product). Precipitation of reactive minerals, including calcite, occurs in groundwater under near neutral pH conditions. Figure 3-5 shows saturation indices for calcite versus calcium and bicarbonate concentrations (millimoles/liter) at selected background springs and wells. The computer program MINTEQA2 (Allison et al., 1991) was used to perform SI calculations. For a given solid phase at equilibrium, the SI is equal to 0 ± 0.05. Oversaturation (positive SI) implies precipitation, whereas undersaturation (negative SI) implies dissolution. Native alluvial and perched intermediate groundwaters are calculated to be undersaturated with respect to calcite, and dissolution of this mineral takes place. This is consistent with the absence of calcite within the natural alluvium at the Laboratory. Groundwater samples collected at wells R-9, R-12, and Otowi-4 and La Mesita Spring generally are saturated with respect to calcite, whereas LAOI(A)-1.1 is not. Activities of dissolved calcium and bicarbonate at well LAOI(A)-1.1 are not sufficient to precipitate calcite. Calcite typically is not observed in native groundwater within the alluvium and Bandelier Tuff. The regional aquifer (Santa Fe Group sediments) is slightly undersaturated, but within thermodynamic uncertainty, with respect to calcite.

3.1.4 Adsorption and Precipitation Reactions

Adsorption occurs when dissolved species interact with surfaces of aquifer material coated with hydrous ferric oxide, manganese dioxide, clay minerals, or other adsorbents. Adsorption is usually reversible with the net effect being that the transport of the absorbed species is much slower than that of the water. Hydrous ferric oxide is an important adsorbent present in different aquifer materials beneath the Pajarito Plateau. Other adsorbents of metals include smectite, calcite, manganese oxide, and solid organic carbon, which can provide additional adsorption sites on aquifer material and within the unsaturated zone. Hydrous ferric oxide has a specific surface area of 600 m^2/g, which is much higher than quartz or silica gel that have specific surface areas of 0.14 and 53 to 292 m^2/g, respectively (Langmuir, 1997). Many metals and radionuclides including barium, chromium, nickel, uranium, strontium-90, americium-241, plutonium-238, and plutonium-239, -240 typically adsorb onto hydrous ferric oxide-coated particles between pH values 5 and 8.

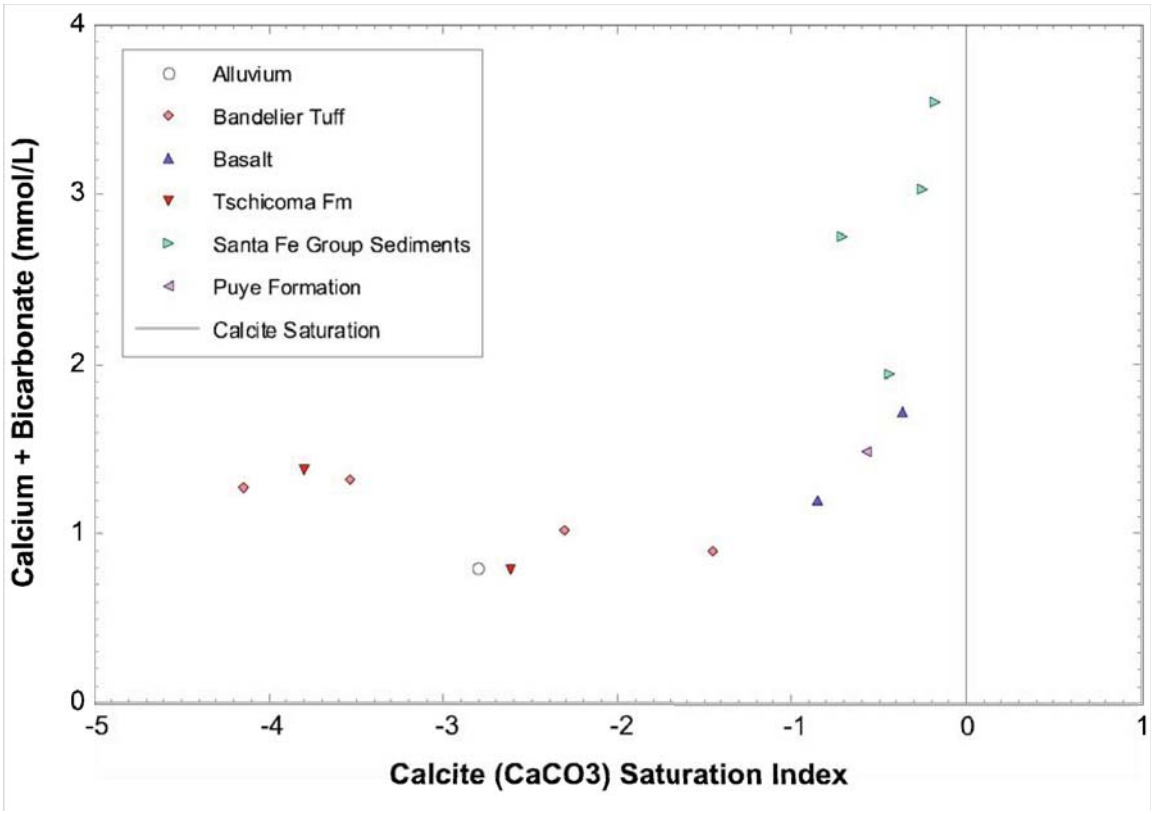

Figure 3-5. Saturation indices for calcite versus calcium and bicarbonate concentrations (millimoles/liter) at springs and wells representing different aquifer types at LANL (perched, intermediate, and regional).

Concentrations of inorganic contaminants (actinides, fission products, and trace elements) remaining within treated effluents are too small to be removed from solution through precipitation, based on results of computer simulations. Downgradient from Laboratory discharge points, adsorption processes are considered to dominate over mineral precipitation for continual removal of metals and radionuclides from alluvial groundwater. As a result, concentrations of adsorbing radionuclides and inorganic species generally decrease downgradient along the groundwater flow path. Alluvial material provides the largest reservoir for constituents from treated Laboratory effluent, including strontium-90, cesium-137, plutonium-238, plutonium-239, -240, and americium-241 because the constituents readily adsorb onto clay- and silt-sized material. For example, it is hypothesized that strontium-90 has been reversibly adsorbed on alluvial sediments by cation exchange, and the sediments provide a continuing source of this constituent to the alluvial groundwater. Eventually, strontium-90 will decay to stable zirconium-90 (via short-lived yttrium-90), reducing its remaining radioactivity by a factor of two approximately every 29 years.

Based on numerous studies reported in the literature, and supported by field observations documented in LANL Surveillance Reports (e.g. LANL, 1996a, 2000a, 2001a, 2002) and

experimental results, the relative adsorption of HE compounds, radionuclides and inorganic species decreases at circumneutral pH (6 to 8) conditions as follows:

cesium-137 (highest adsorption) = americium-241 > barium > strontium-90 > uranium > nitrate = molybdate = sulfate = chloride = perchlorate = TNT > RDX = tritium (lowest adsorption).

Cations adsorb more strongly than anions under acidic to circumneutral pH conditions because adsorbents, including hydrous ferric oxide, smectite, and silica glass, are characterized by a net-negative surface charge (Langmuir, 1997). (Oxy)anions, including molybdate, nitrate, and perchlorate, are mobile in groundwater under circumneutral to basic pH conditions due to the net-negative surface charge on the adsorbent. Neutral species including TNT, RDX, and tritium do not adsorb to any significant extent onto inorganic mineral surfaces. Characterization and surveillance data collected within Pueblo Canyon, Los Alamos Canyon, Mortandad Canyon, and Cañon de Valle support the observed mobilities of anions (chloride, molybdate, nitrate, perchlorate, sulfate, and uranium) and neutral species (RDX, TNT, and tritium). High explosive compounds undergo hydrophobic sorption with solid organic matter present in alluvial channels, including Cañon de Valle, but such material is not present in significant concentrations in the regional aquifer.

Other variables that influence adsorption processes include precipitation and dissolution of the adsorbent, adsorption capacity, and changes in aqueous chemistry. Adsorption capacities of unsaturated and saturated material may change over time due to changes in solution composition, contaminant speciation and reactive phase mineralogy. In isolated cases where effluent discharges have changed alluvial groundwater alkalinity or pH, trace elements such as strontium and barium may precipitate as $SrCO_3$, $BaCO_3$, and coprecipitate as $(Sr\text{-}Ba)SO_4$. These precipitation processes are considered to be important within the upper reaches of Cañon de Valle and Mortandad Canyon.

Cation exchange reactions typically influence major cation compositions of groundwater. This influence is especially true for older groundwater with a long residence time characteristic of the regional aquifer east of the Rio Grande. Cation exchange between divalent, magnesium and calcium and monovalent sodium results in increasing water hardness (increased calcium and magnesium) in which calcium typically dominates over magnesium as the dominant dissolved cation. Softening of water occurs when calcium and magnesium are removed from groundwater and sodium becomes the dominant cation. This water-softening process is observed northeast of the Laboratory (former lower Los Alamos wellfield) and along sections of the Rio Grande.

3.1.4.1 Adsorption and Precipitation of Uranium(VI) Species

Uranium is a naturally occurring trace element found in groundwater and it is also processed at the Laboratory. This subsection provides a summary of the aqueous chemistry and adsorptive characteristics of this actinide because of its importance to background conditions and Laboratory effluents.

Uranium is a naturally occurring actinide found essentially in all soils, sediments, rocks, surface waters, and groundwaters worldwide. Whole rock concentrations of uranium within the Bandelier Tuff, Cerros del Rio basalt, and Puye Formation range from less than 1 to over 10 mg/kg or ppm (Longmire et al. 1996a, Broxton et al. 2001a). Silica-rich rocks, including the Bandelier Tuff, contain higher concentrations of uranium than do the less siliceous rocks, including the Cerros del Rio basalt and Puye Formation.

Background concentrations of dissolved uranium within alluvium, perched intermediate zones, and the regional aquifer are generally detectable but at concentrations less than 1 μg/L in groundwater beneath the Pajarito Plateau (Longmire et al., 1996b, LANL 2005a). These naturally low concentrations of dissolved uranium are probably controlled by aqueous solubilities of minerals containing uranium. For example, zircon ($ZrSiO_4$) is a trace mineral found within the Bandelier Tuff. Concentration of uranium in a zircon crystal within a sample of the Bandelier Tuff was 1180 ppm (Stimac et al. 1996). This highly refractory mineral has an aqueous solubility of $10^{-15.4}$ M at pH 7. Uranium does not significantly leach out of this mineral at circumneutral pH values (6 to 9) based on its low aqueous solubility. Some uranium concentrated within the Bandelier Tuff is associated with volcanic glass, which has an aqueous solubility of $10^{-2.71}$ M at pH 7. Consequently, there is higher occurrence of uranium in groundwater within the Bandelier Tuff because it is more susceptible to leaching from glass due to its higher aqueous solubility. The rate of uranium leaching from glass, however, is slow, as indicated by the low dissolved concentrations of uranium (<0.5μg/L) measured in perched groundwater within the Bandelier Tuff (well LAOI(A)-1.1).

The uranyl (UO_2^{2+}) cation is analogous to other divalent metal species that significantly adsorb onto hydrous ferric oxide under acidic pH conditions. Increasing concentrations of hydrous ferric oxide result in increasing the adsorption capacity of uranium(VI) complexes because more binding sites are present. Concentrations of hydrous ferric oxide vary between alluvial groundwater, perched intermediate zones, and the regional aquifer. This variation is dependent on chemical weathering of primary iron-rich minerals and iron-rich volcanic glass. Iron-rich glass and minerals within the Cerros del Rio basalt enhance precipitation of increasing amounts of hydrous ferric oxide compared to the Bandelier Tuff, which contains iron-depleted glass and smaller amounts of iron-bearing minerals.

The computer program MINTEQA2 (Allison et al., 1991) was used to model adsorption (surface complexation) of uranium(VI) onto hydrous ferric oxide for perched intermediate groundwater characterized at well R-9. The double layer model (DLM) was selected for the simulation because it takes into account adsorbent characteristics (specific surface area, charge density, and adsorbent concentration) and aqueous chemistry parameters (pH, ionic strength, and solution composition).

Figure 3-6 shows both calculated distributions of adsorbed uranium(VI) complexes onto hydrous ferric oxide and dissolved complexes as a function of pH. Results of the calculation suggest that maximum adsorption takes place at pH 5.5 and decreasing adsorption occurs with increasing pH, which is due to the formation of uranyl carbonate complexes. Uranyl dicarbonate and uranyl tricarbonate complexes do not significantly adsorb onto negatively charged surface sites present

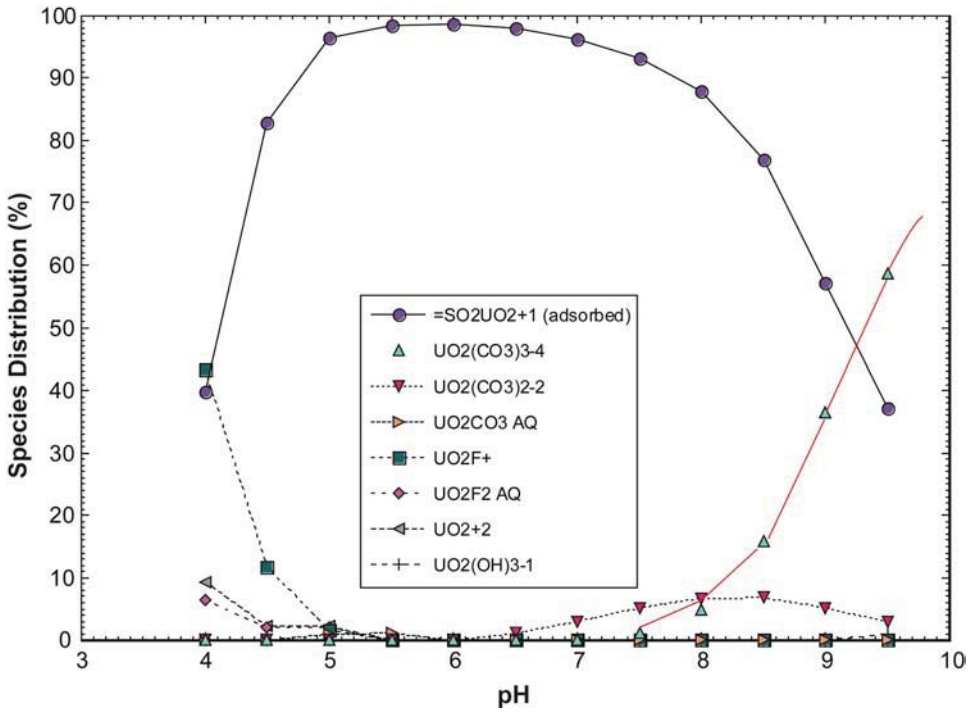

Figure 3-6. Calculated distributions of adsorbed and dissolved uranyl species for well R-9 (275 ft perched zone) (HFO concentration = 1.46 g/L and total dissolved uranyl [UO_2^{2+}] = 0.054 ppm, 25°C). Calculation was made for R-9 because uranium was measured in groundwater whithin the Cerros del Rio basalt.

on hydrous ferric oxide. There is a sharp rise in uranium(VI) adsorption onto hydrous ferric oxide between pH values of 4.0 and 5.0 (Figure 3-6), where uranyl cation species dominate.

Other divalent cations compete with uranyl species in both natural and contaminated groundwater. Calcium (Ca^{2+}) strongly competes with UO_2^{2+} for adsorption sites present on hydrous ferric oxide, based on experimental results, including DLM intrinsic stability constants provided by Langmuir (1997). Concentrations of dissolved calcium are much higher (in the mg/L range) than dissolved uranium (less than 1 μg/L), which allows for more calcium binding onto hydrous ferric oxide.

Similar competition between calcium and the uranyl cation may take place with clay minerals. This has relevance to groundwater chemistry east of the Rio Grande that is characterized by higher concentrations of calcium and uranium compared to groundwater beneath the Pajarito Plateau. This exchange reaction results in concentrations of natural uranium within the regional aquifer ranging from 0.5 μg/L (Los Alamos) to over 1800 μg/L (west of Nambé).

Exchange reactions between calcium and sodium are of importance based on inverse relationships between dissolved calcium, sodium, and uranium. Figure 3-7 shows calcium/sodium ratios (milliequivalents/L) versus uranium concentrations for 127 groundwater samples collected at Pojoaque, New Mexico during June 2004. The highest concentrations of uranium in groundwater occur at lower calcium/sodium ratios. This relationship suggests that

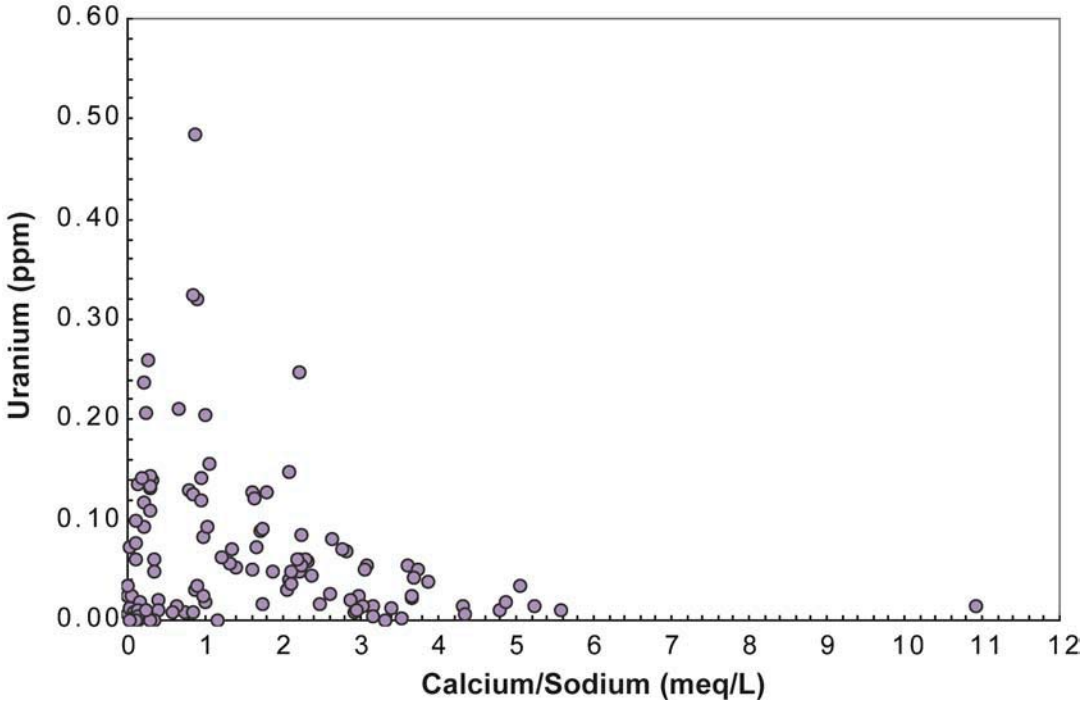

Figure 3-7. Calcium/sodium (meq/L) versus uranium concentrations, Pojoaque water fair, June 2004.

calcium is removed from groundwater, whereas uranium is added to groundwater through cation exchange. Alternatively, the relationship between uranium and sodium/calcium rations could be due to bulk compositional effects rather than cation exchange. In some groundwater samples, calcium is removed to a greater extent than sodium.

Precipitation reactions serve as a sink for removing uranium from solution. There are numerous uranium (VI) minerals that are naturally occurring and are found in aquifers (ore deposits) within sedimentary and igneous rocks. Several uranyl silicate minerals including $(UO_2)_2SiO_4 \cdot 2H_2O$ (soddyite) and $Ca(UO_2)_2(Si_2O_5)_3 \cdot 5H_2O$ (haiweeite) are potentially important within silica-rich groundwater beneath the Pajarito Plateau. Figure 3-8 shows a plot of saturation indices for several reactive minerals including silica solids, carbonate minerals, soddyite, and haiweeite for several groundwater sampling stations including Spring 2B, alluvial well LAO-B, perched intermediate groundwater (well LAOI(A)-1.1), and regional aquifer groundwater (wells Otowi-4, TW-3, R-9, and TW-1). The computer program MINTEQA2 (Allison et al., 1991) was used to perform the saturation calculations.

Temperature, pH, redox potential, and dissolved activities of calcium, uranium(VI), bicarbonate, and silicic acid influence the precipitation/dissolution of soddyite and haiweeite. As bicarbonate concentrations increase, dissolved uranium(VI) reacts to form complexes, which decreases the amount of uranyl cation (UO_2^{2+}) available for precipitation of soddyite and haiweeite. This is counter balanced, however, by increasing concentrations of dissolved calcium that enhances precipitation of haiweeite at Otowi-4, R-9, TW-1, and Spring 2B (Figure 3-8). This assessment is

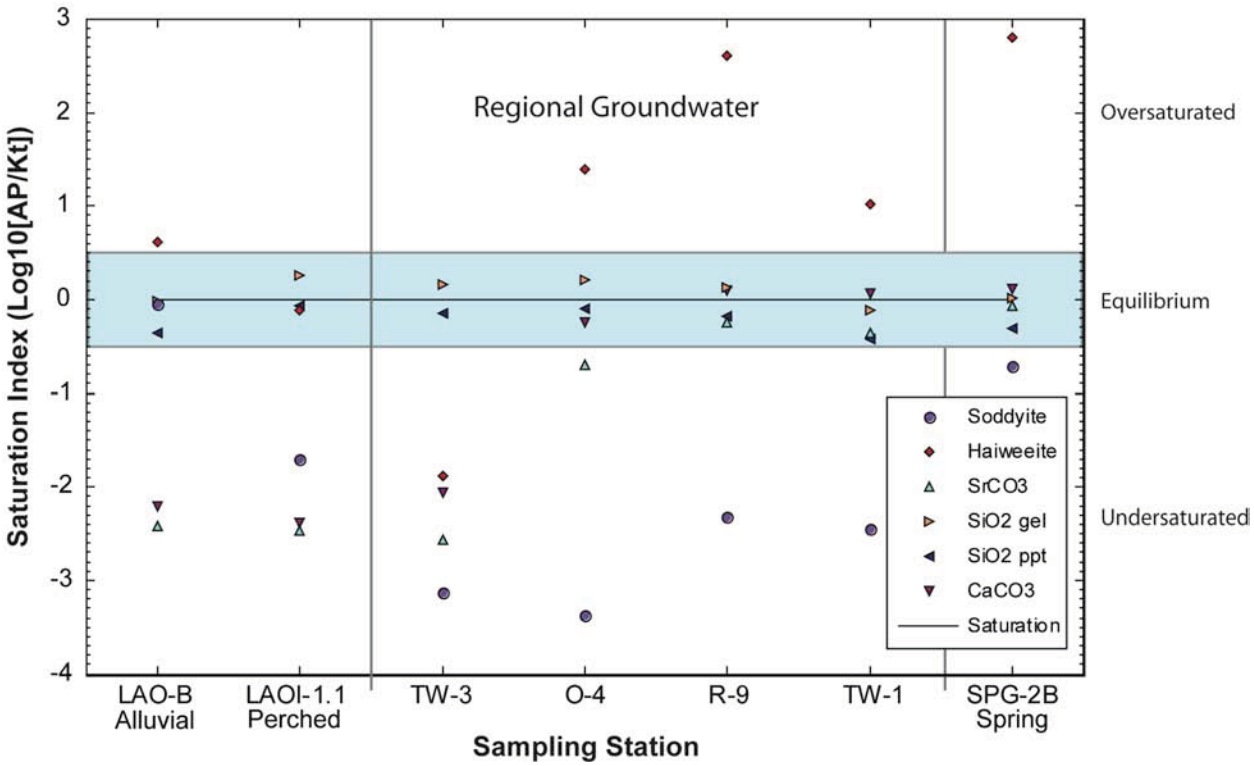

Figure 3-8. Saturation indices for several solid phases in alluvial (LAO-B) and perched intermediate groundwater (LAOI(A)-1.1) and the regional aquifer (Otowi-4, TW-3, R-9 and TW-1) within Los Alamos Canyon, Pueblo Canyon, and Spring 2B. The computer program MINTEQA2 was used to perform the calculations. Note: These wells were selected because they show hyrochemical snapshot of the three aquifer types within the Los Alamos Canyon and a spring.

based on geochemical calculations and the overall oxidizing conditions characteristic of natural groundwater beneath the Pajarito Plateau.

While it is useful to perform saturation index calculations to evaluate mineral equilibrium, most of the deep groundwaters are not in equilibrium with respect to either soddyite or haiweeite. Based on results of the calculations presented, adsorption processes involving uranium(VI) appear to control dissolved concentrations of this actinide in groundwater beneath the Pajarito Plateau.

3.1.5 Redox Conditions

This subsection presents a brief discussion on oxidation-reduction concepts with application to groundwater chemistry characterized during this investigation. Contaminants associated with treated Laboratory effluents that are stable in more than one oxidation state include plutonium(III, IV, V, and VI), uranium(IV and VI), technetium(IV and VII), iron(II and III), and chromium(III and VI). Other contaminants that can undergo reduction include perchlorate,

molybdate, nitrate, RDX, and TNT. A group of contaminants that is stable in one oxidation state under the geochemical conditions that prevail in groundwater includes americium(III)-241, cesium(I)-137, strontium(II)-90, barium(II), boron(III), and tritium(I). Adsorption and precipitation reactions involving redox-sensitive contaminants are directly influenced by oxidation and reduction reactions. Under oxidizing conditions, species including uranium(VI), sulfate, nitrate, and perchlorate form soluble anions that are mobile in groundwater. Under reducing conditions, however, these species either precipitate from solution (uranium and sulfide minerals), transform (perchlorate) and/or adsorb onto aquifer materials (nitrogen-ammonium).

Oxidation-reduction (redox) reactions are very important in groundwater systems for controlling distributions of trace elements and are quite often mediated by a wide variety of microbes. Redox conditions for groundwater most often cannot be quantified with a single redox couple and oxidation-reduction potential (ORP) (Langmuir, 1997) because numerous couples are present and they differ with respect to kinetic reaction rates (Figure 3-9). Some couples are electrochemically reversible, including the iron(III)/iron(II) and hydrous ferric oxide/iron(II) pairs. However, most pairs are not reversible under normal groundwater conditions in the absence of microbes, including: dissolved oxygen/water, nitrogen (V)/nitrogen(0), nitrogen(V)/nitrogen(III), uranium(VI)/uranium(IV), sulfur(VI)/sulfur(-II), and carbon(IV)/carbon(0, -IV). General trends in redox chemistry, however, can be inferred based on distribution and concentration of redox-sensitive solutes such as iron and manganese, mineralogy of aquifer material, presence or absence of dissolved oxygen, knowledge of microbial populations, and presence of electron donors (reducing agents, reductants), and electron acceptors (oxidizing agents, oxidants).

Under natural or baseline conditions, groundwater under the Pajarito Plateau within perched intermediate zones and the regional aquifer is oxidizing. This is also generally true for alluvial groundwater, although DOC may enhance localized reducing conditions within wetlands occupying some canyon reaches. Naturally occurring and measurable concentrations of dissolved oxygen (DO) (1 to 9 ppm), sulfate (>2 ppm), and nitrate (typically 0.5 ppm) are characteristic of oxidizing conditions. Low concentrations of dissolved iron (<0.5 ppm) and manganese (<0.05 ppm) are also characteristic of oxidizing conditions. Under reducing conditions, concentrations of reduced forms of carbon (methane, hydrocarbons, carbohydrates), nitrogen (ammonium), and sulfur (hydrogen sulfide) would exceed concentrations of the oxidized forms. Iron and manganese reduction would also be observed under reducing conditions. Reducing conditions do not occur in normal groundwater beneath the Pajarito Plateau although they have been encountered in several R wells as a highly localized consequence of residual drilling fluids, as described by Longmire and Goff (2002) and Longmire (2002a, 2002b, 2002d, and 2002e) and Bitner et al. (2004) in detail.

3.1.6 Uranium Speciation

Chemical speciation has a direct control on mineral precipitation and adsorption processes. Special attention is given to uranium in this report because this actinide occurs naturally in groundwater and has also been processed at the Laboratory. Large variations in natural uranium concentrations are observed beneath the Pajarito Plateau and to the east in the Rio Grande Valley.

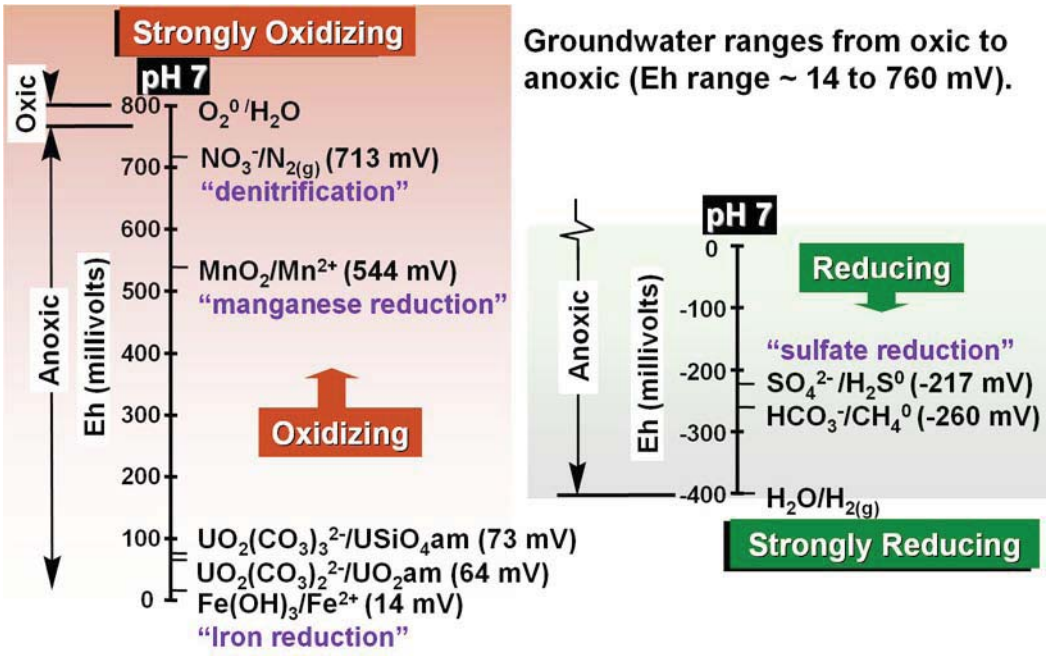

Figure 3-9. Selected oxidation-reduction couples in water at pH 7 and 25°C for the Pajarito Plateau and surrounding areas.

As uranium leaches from minerals and glass, it is stable as uranium(VI) under oxidizing conditions characteristic of aquifer systems beneath the Pajarito Plateau. Uranium(VI) forms strong complexes with bicarbonate and carbonate including $UO_2CO_3^0$, $UO_2(CO_3)_2^{2-}$, and $UO_2(CO_3)_3^{4-}$ (Langmuir 1997) above pH 6.

Figure 3-10 shows calculated distribution of uranium(VI) at Spring 9B discharging from the Cerros del Rio basalt east of the Laboratory. Dissolved concentrations of uranium are typically less than 0.2 µg/L at Spring 9B (LANL 1996a, 2000a, 2001a, 2002).The computer program MINTEQA2 (Allison et al., 1991) was used for the speciation calculations of Spring 9B. The aqueous complex, $UO_2(CO_3)_3^{4-}$ dominates above pH 8.4, whereas $UO_2(CO_3)_2^{2-}$ dominates between pH values of 6.6 and 8.4 at Spring 9B (Figure 3-10). Dissolved uranyl carbonate ($UO_2CO_3^0$) dominates between pH values of 5.0 and 6.6. Spectroscopic evidence has shown that $Ca_2UO_2(CO_3)_3^0$ significantly influences uranium(VI) speciation between pH values of 6 to 10 in calcium-rich uranium-mining waters (Bernhard et al., 2001). This complex may have relevance to groundwater east of the Rio Grande characterized by high calcium and carbonate alkalinity.

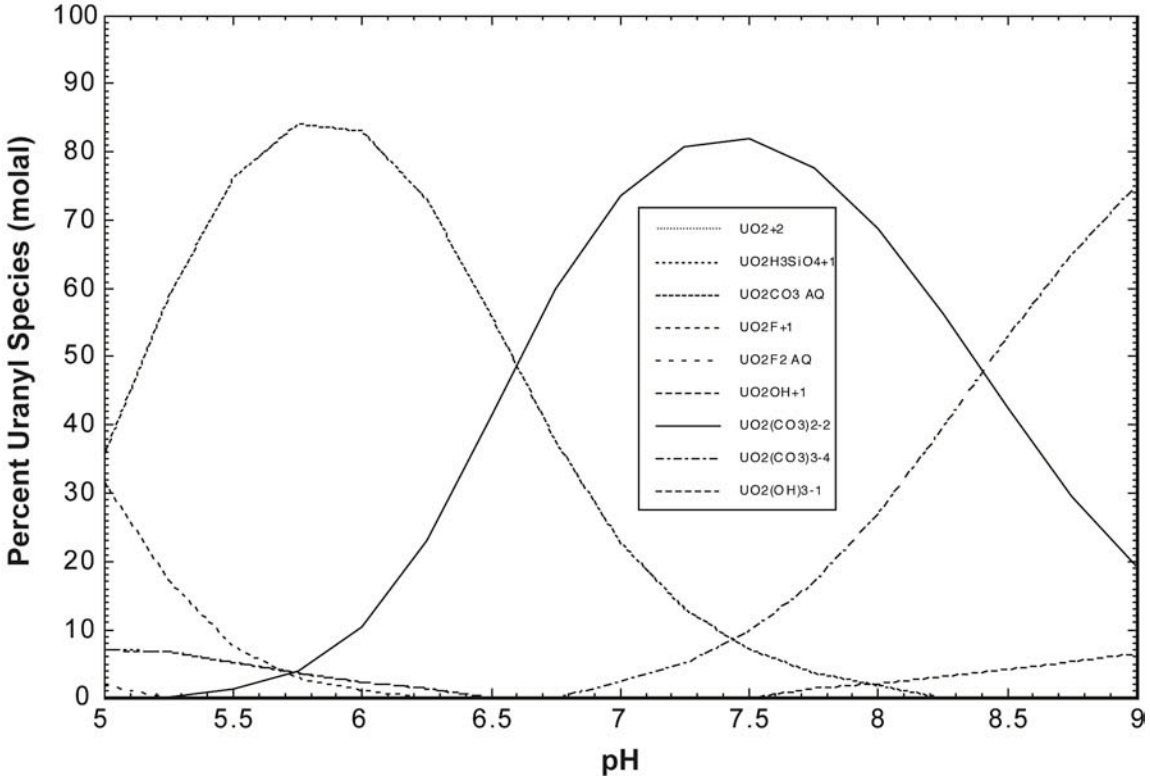

Figure 3-10. Results of speciation calculations for Spring 9B in White Rock Canyon using the computer program MINTEQA2. Log U(VI) = -9.26 molal (m), log F = -4.69 m, log H_4SiO_4 = -2.92 m, and log CO_3^{2-} = -3.07 m at 20.5°C.

Figure 3-11 shows total alkalinity versus uranium concentrations for 127 groundwater samples collected within the Rio Grande Valley near Pojoaque, New Mexico, contrasted with samples from the Pajarito Plateau. Formation of uranyl carbonate complexes has a direct control on the solubility of uranium(VI), leading to dissolved concentrations of uranium much greater than 10 µg/L observed in the Rio Grande Valley.

Uranium(IV) is stable in strongly reducing groundwater containing dissolved sulfide and reduced forms of DOC (Langmuir 1997). Calculations show that uranium(IV) in the form of $U(OH)_4^0$ is stable under reducing conditions below an Eh of –225 millivolts (mV) at pH 7, 25°C, and $10^{-3.0}$ M (61 mg/L) bicarbonate. Formation of uranium(IV) complexes is very unlikely to occur because natural groundwater at Los Alamos, New Mexico is oxidizing and uranium(VI) species are stable. However, in groundwater near Pojoaque uranium(IV) is inferred to be stable in the presence of hydrous ferric oxide reduction.

3.1.7 Summary of Geochemical Conceptual Model

It is important to understand geochemical processes and the natural water quality beneath the Pajarito Plateau, so that anthropogenic perturbations to the natural system can be identified and quantified. While the contaminants are at concentrations largely below regulatory standards or

risk levels, they demonstrate the presence of pathways for groundwater flow and contaminant transport from the surface to deeper groundwater.

Natural groundwater (alluvial, intermediate, and regional aquifer) ranges from calcium-sodium bicarbonate composition within the Sierra de los Valles to a sodium-calcium bicarbonate composition east and northeast of the Laboratory. The Sierra de los Valles provides most of the recharge to groundwater beneath the Pajarito Plateau and groundwater in the recharge area has the lowest TDS of the overall flow system.

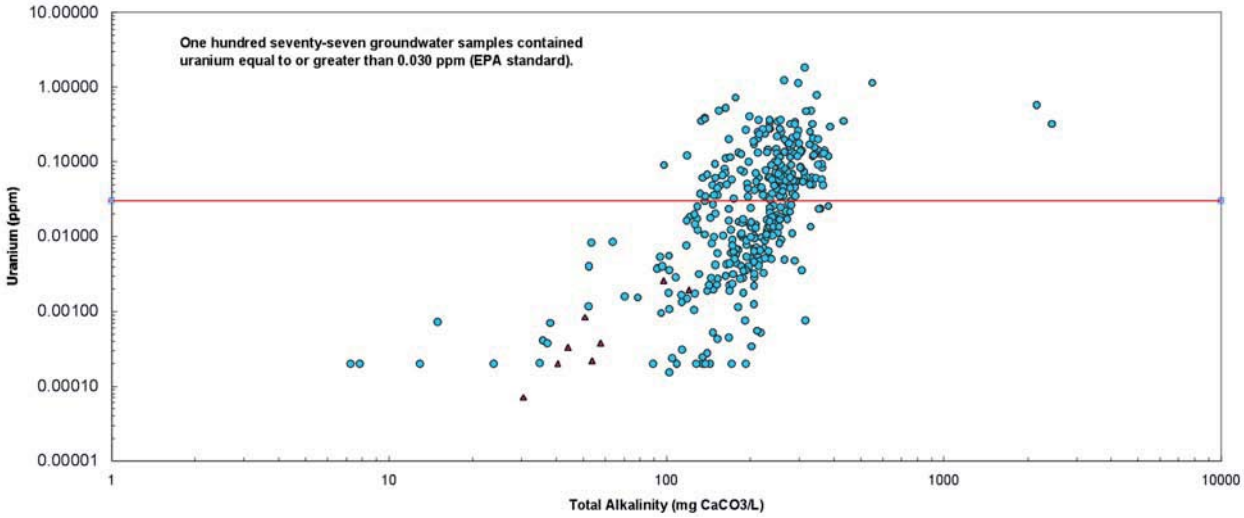

Figure 3-11. Total alkalinity (as carbonate) versus uranium concentrations in groundwater samples collected from the Rio Grande Valley and the Pajarito Plateau. Red triangles are from Pajarito Plateau and blue dots are from the Rio Grande Valley.

Along flow paths variation in solute concentration results from mixing of groundwaters, mineral precipitation (solute sink), mineral dissolution (solute source), and adsorption/desorption reactions. Calcium, sodium, and bicarbonate are the dominant major ion solutes in natural groundwater beneath the Pajarito Plateau and surrounding areas. Silica is the second most abundant solute found in surface water and groundwater within the Los Alamos area because of hydrolysis reactions taking place between soluble silica volcanic glass and water. Variations in groundwater trace element concentrations depend on solute residence time, speciation, and extent of water-rock interactions.

All of the mobile chemicals measured in perched intermediate zones and in the regional aquifer are stable as anions (perchlorate, nitrate, sulfate, chloride, uranium) or as neutral species (RDX, TNT, HMX, boron). Contaminants stable as cations (barium, americium-241, plutonium(V)-238, -239, -240, strontium-90, cesium-137) have migrated within alluvial groundwater and are infrequently detected in deeper groundwater.

Groundwater within a discharge zone, at the end of groundwater flow paths, generally has the highest mineral or solute content and also represents the oldest water. Residence times of groundwater and chemical solutes increase both with depth and from west to east across the Pajarito Plateau within each groundwater zone. The oldest groundwater residence times within the regional aquifer are on the order of several thousand to tens of thousands of years, based on carbon-14 dating and on flow and transport models.

Geochemical processes that affect the groundwater chemistry include the following:

- ***Precipitation/Dissolution***: Different reactive minerals and amorphous solids precipitate or dissolve and can control the major ion composition of groundwater. As groundwater flows through perched intermediate zones and the regional aquifer, chemical and mineralogical compositions of reactive phases including silica glass change over time. For example, silica glass is the most soluble component of the aquifer material reacting with groundwater to form clay minerals, including kaolinite and smectite. Precipitation reactions serve as a sink for removing uranium from solution.
- ***Adsorption:*** Dissolved species interact with surfaces of aquifer material coated with hydrous ferric oxide, manganese dioxide, clay minerals, or other adsorbents, often resulting in the release of adsorbed species via replacement reactions. Hydrous ferric oxide is an important adsorbent present in different aquifer materials beneath the Pajarito Plateau. Other common adsorbents of metals include smectite, calcite, manganese oxide, and solid organic carbon. Downgradient from Laboratory discharge points, adsorption processes are considered to dominate over mineral precipitation for continual removal of metals and radionuclides from alluvial groundwater. Adsorption processes involving uranium(VI) appear to control dissolved concentrations of this actinide in groundwater beneath the Pajarito Plateau.
- ***Redox Conditions***: Under natural or baseline conditions, groundwater under the Pajarito Plateau within alluvial, perched intermediate zones, and the regional aquifer is oxidizing. Adsorption and precipitation reactions involving redox-sensitive contaminants are directly influenced by oxidation and reduction reactions. Under oxidizing conditions, species including uranium(VI), sulfate, nitrate, and perchlorate form soluble anions that are semimobile in groundwater. Uranium(VI) partly adsorbes onto ferric oxyhydroxide and is semimobile in groundwater between a pH range of 7 to 8.5, typically observed in groundwaters of the Pajarito Plateau. Under reducing conditions, however, these species either precipitate from solution (uranium and sulfide minerals), transform (perchlorate) and/or adsorb onto aquifer materials (nitrogen-ammonium).
- ***Chemical Speciation***: has a direct control on mineral precipitation and adsorption processes. Formation of uranium(IV) complexes is very unlikely to occur because natural groundwater at Los Alamos, New Mexico is oxidizing and uranium(VI) species are stable.

3.2 Contaminant Distributions and Transport

This section describes the sources, presence, and trends through time of chemical constituents in groundwater originating from anthropogenic (principally LANL) sources. The movement rates and distribution of these chemical constituents give an indication of groundwater flow paths and flow mechanisms over time. Appendix 3-A provides a description and map of each canyon, arranged by watershed, because this framework highlights the connection between surface liquid discharge sources and their effects on shallow and deeper groundwater chemistries.

In this section anthropogenic chemical constituents found in groundwater are divided into two classes: contaminants and other anthropogenic chemical constituents. Contaminants in groundwater are chemicals found at concentrations near or exceeding either regulatory standards or, where no standards exist, exceeding EPA screening levels of either hazard index (HI) of 1 or excess cancer risk of 10^{-5}. For chemicals with no standards, the EPA Region VI tap water screening levels were used (http://www.epa.gov/earth1r6/6pd/rcra_c/pdn/screen.htm). For cancer-causing substances, the Region VI tap water screening levels are at a risk level of 10^{-6}, therefore, 10 times these values were used to screen for a risk level of 10^{-5}. A hazard index value of 1 or less indicates that no (noncancer) adverse human health effects are expected to occur.

Anthropogenic chemical constituents other than contaminants are found at lower concentrations, although some of these constituents may have been contaminants (that is, at higher concentrations) in the past.

Table 3-1 summarizes the anthropogenic constituent observations in alluvial, intermediate, and regional aquifer groundwater. Information on Table 3-1 indicates that most canyons with anthropogenic constituents in alluvial groundwater also have anthropogenic constituents in the intermediate (if present) and the regional aquifer. The water quality impacts of effluent releases on alluvial groundwater extend to perched groundwater at depths of a few hundred feet beneath these canyons. The contaminated perched groundwater bodies are separated from the regional aquifer by hundreds of feet of dry rock, and in these wet canyons recharge from the shallow perched groundwater occurs in a time frame of decades. Nevertheless, the magnitude of water quality impacts on the regional aquifer are quite low.

Table 3-1.
Summary of Factors Influencing Contaminant Distributions in Groundwater at Los Alamos National Laboratory

Canyon	Presence of Contaminant Sources	Water Inputs		Hydrogeologic Controls			Observed Contaminants in Groundwater		
		Natural	Anthropogenic	Enhanced Infiltration	Potential Lateral Pathways	Flow Field Modification	Alluvial	Intermediate	Regional Aquifer
Guaje	Minor dry sources	Low	None	Puye Formation exposed in canyon bottom	None	Near Guaje wellfield	None	No intermediate groundwater	None
Bayo	Previous sources removed; little present source	Low	Low	None, basalts not present in vadose zone	None, basalts not present in vadose zone		No alluvial groundwater present	No intermediate groundwater present	None
Pueblo (including Acid Canyon)	Multiple, liquid sources	Low	High, POTW effluent-supported stream	Yes, associated with faults	No, basalts not present in vadose zone	O-1 located in Pueblo Canyon	Nitrate, boron, tritium (past); Strontium-90	Tritium (TW-2A); nitrate (TW-1A)	Perchlorate (O-1), tritium (O-1, R-4), nitrate (TW-1, O-1, R-4)
Los Alamos (including DP)	Multiple liquid sources	Moderate	High, effluent discharges	Yes, Cerros del Rio basalt exposed in canyon bottom at R-9	Yes, Cerros del Rio basalt present in vadose zone	O-4 located in Los Alamos Canyon	Strontium-90; molybde-num, tritium, plutonium-239, -240, -248	Tritium (LADP-3, R-9i,R-6i); nitrate (R-6i)	Tritium (TW-3, R-9, R-6)
Sandia	Multiple liquid sources	Low	High, effluent discharges	Yes, Cerro Toledo Member exposed in canyon bottom near PM-1	Yes, Cerros del Rios basalts within shallow vadose zone	PM-1 and PM-3 located in Sandia Canyon	Alluvial groundwater not present	Tritium (R-12, R-7), nitrate (R-12)	Tritium (R-12, R-11), nitrate (R-12, R-11)

Table 3-1.
Summary of Factors Influencing Contaminant Distributions in Groundwater at Los Alamos National Laboratory (continued)

Canyon	Presence of Contaminant Sources	Water Inputs		Hydrogeologic Controls			Observed Contaminants in Groundwater		
		Natural	Anthropogenic	Enhanced Infiltration	Potential Lateral Pathways	Flow Field Modification	Alluvial	Intermediate	Regional Aquifer
Mortandad	Multiple liquid sources	Low	High, effluent discharges	Thick pockets of alluvium; sediment ponds	Extensive Cerros del Rio basalt in vadose zone	Within PM wellfield	Americium-241, plutonium-238, plutonium-239, -240, strontium-90, tritium, nitrate, perchlorate, fluoride	Tritium (MCOBT-4.4, R-15), nitrate (MCOBT-4.4), perchlorate (MCOBT-4.4, R-15)	Tritium (R-15, R-28), nitrate (R-15, R-28), perchlorate (R-15)
Canada del Buey	Major dry sources; minor liquid sources	None	None on LANL property; effluent from White Rock POTW	No, canyon bottom underlain by Bandelier Tuff	Extensive Cerros del Rio basalt close to surface	Within PM wellfield	Gross alpha, gross beta	No intermediate perched groundwater is present	None
Pajarito Canyon	Major dry sources	High	Moderate	Yes, Cerros del Rio basalt exposed at the surface from west of R-23 to Rio Grande	Yes, extensive Cerros del Rio basalt	Yes, within PM wellfield	Metals, radio-nuclides, HE, VOCs and anions	HE (springs)	None
Water	Multiple dry and liquid sources in upper part of canyon	High	High	Yes, Cerros del Rio basalt exposed in lower part of canyon	Yes, extensive Cerros del Rio basalts in lower canyon	None	HE, barium		

Table 3-1.
Summary of Factors Influencing Contaminant Distributions in Groundwater at Los Alamos National Laboratory (continued)

Canyon	Presence of Contaminant Sources	Water Inputs		Hydrogeologic Controls			Observed Contaminants in Groundwater		
		Natural	Anthropogenic	Enhanced Infiltration	Potential Lateral Pathways	Flow Field Modification	Alluvial	Intermediate	Regional Aquifer
Cañon de Valle	Multiple dry and liquid sources in upper part of canyon	High	High	No, underlain by thick Bandelier Tuff	Yes, Cerro Toledo interval in vadose zone	None	Barium, HE, perchlorate	HE, barium,	Tritium (R-25), HE(?) (R-25)
Potrillo/ Fence	Minor dry sources	Low	None	No, underlain by Bandelier Tuff	Yes, extensive Cerros del Rio basalt in vadose zone	None	No, alluvial groundwater not present	No, intermediate perched groundwater not present	None

Summary of Factors Influencing Contaminant Distributions in Groundwater at Los Alamos National Laboratory (continued)

Canyon	Presence of Contaminant Sources	Water Inputs		Hydrogeologic Controls			Observed Contaminants in Groundwater		
		Natural	Anthropogenic	Enhanced Infiltration	Potential Lateral Pathways	Flow Field Modification	Alluvial	Intermediate	Regional Aquifer
									perchlorate, uranium (Spring 2B)

3.2.1 Contaminant and Constituent Sources

Table 3-1 indicates the factors that have primary influence on distribution of anthropogenic constituents in groundwater. The first factor is the presence of upgradient sources of these constituents. The sources affecting groundwater at the Laboratory are mainly liquid effluents rather than solid waste disposal or other activities. Since the 1940s, liquid effluent disposal by the Laboratory has degraded water quality in the shallow perched groundwater that underlies a few canyons (Figure 3-12). Drainages that received significant radioactive effluent discharges are Mortandad Canyon and Pueblo Canyon from its tributary Acid Canyon, and Los Alamos Canyon from its tributary DP Canyon. Rogers (2001) and Emelity (1996) summarize radioactive effluent discharge history at the Laboratory. Water Canyon, its tributary Cañon de Valle, and Pajarito Canyon have received effluents produced by HE processing and experimentation (Glatzmaier 1993, Martin 1993, LANL, 1998a). Over the years, Los Alamos County has operated three sanitary treatment plants in Pueblo Canyon (LANL, 1981). Only the Bayo plant is currently operating. The Laboratory has also operated numerous sanitary wastewater treatment plants, as shown in Figure 3-12.

Solid waste disposal has less potential to affect groundwater. Most solid waste disposal sites are located on mesa tops where there is little natural or artificial percolation to carry anthropogenic constituents to groundwater. Canyons that have little or no source of anthropogenic constituents (Guaje, Bayo, Potrillo, Fence, Ancho, Chaquehui, and Frijoles) have no anthropogenic constituents in groundwater (Table 3-1). Canyons that had small volume liquid sources or major dry sources are Cañada del Buey and Pajarito Canyon (Table 3-1).

3.2.2 Water Inputs

The second factor influencing anthropogenic constituent distribution in groundwater shown on Table 3-1 is water input, either natural or anthropogenic. The amount of water in a canyon system is a determining factor for transporting anthropogenic constituents. In most cases where Laboratory anthropogenic constituents are found at depth, the setting is one of the following:

- canyons where natural water input is high (Pajarito Canyon, Water Canyon, and Cañon de Valle);
- canyons where anthropogenic water input is high (Pueblo, Los Alamos, Sandia, Mortandad Canyons); or
- mesa-top sites where large amounts of liquid effluent have been discharged (such as retention ponds or outfalls) (mesa tops bounded by Cañon de Valle and Water Canyon).

The presence of water, either natural or from the discharge of effluents to canyons or mesa-top locations in the Laboratory's semiarid setting initiates or increases downward percolation of water. Even under unsaturated flow conditions, this percolation may move significant volumes of water to the regional aquifer within a few decades.

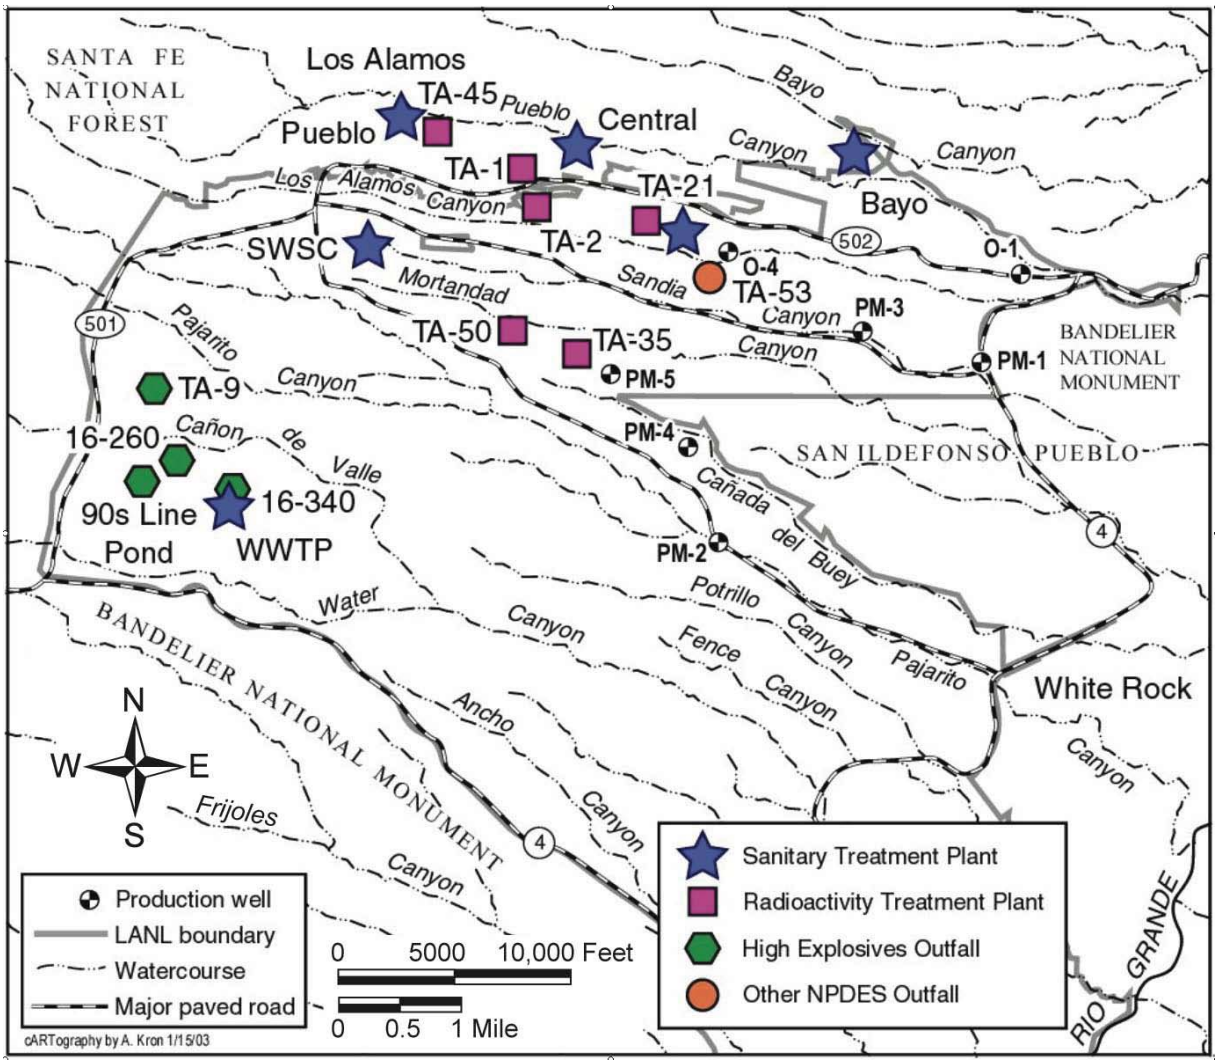

Figure 3-12. Major liquid release sources that have potentially affected groundwater at Los Alamos National Laboratory. Most of these sources are now inactive.

3.2.3 Hydrogeologic Controls

The third factor that contributes to anthropogenic constituent distribution consists of hydrogeologic controls on groundwater pathways and travel rates (Table 3-1). The controls considered most important in influencing contaminant distribution and transport are infiltration at the surface and transport of contaminants in alluvial groundwater, pathways in the vadose zone and transport through intermediate perched groundwater, and flow field modification in the regional aquifer.

The movement of groundwater contaminants is best seen through the distribution of conservative (that is, non-reactive) chemical species. Under most conditions, compounds like RDX, tritium, perchlorate, and nitrate move readily with the groundwater. In many settings, chemical reactions do not retard the movement of these compounds or decrease their concentrations, although the

activity of tritium does decrease due to radioactive decay. For some compounds or constituents (uranium, strontium-90, barium, some HE compounds, and solvents) movement is slowed or their concentrations are decreased by adsorption or cation exchange, precipitation or dissolution, chemical reactions like oxidation/reduction, or radioactive decay. Other constituents (americium-241, plutonium, and cesium-137) are nearly immobile because they are strongly adsorbed onto sediment particles.

3.2.3.1 Infiltration Rate and Transport in Alluvial Groundwater

The first hydrogeologic control, infiltration rate, affects the movement of anthropogenic constituents from the surface to groundwater. As described in Section 2.5.3, undisturbed Bandelier Tuff has a very low infiltration rate. Areas that have other geologic units (particularly basalt units) exposed in the canyon bottom have higher, or enhanced, infiltration rates. Anthropogenic alterations can also enhance infiltration, for example sediment ponds in Mortandad Canyon and ponds in the Cañon de Valle watershed.

The alluvial groundwater present in several canyons has a small volume relative to the annual volume of runoff or effluents, does not extend beyond the LANL boundary, and is generally completely refreshed by recharge on a time scale of about a year (Section 2.4.1). This rapid turnover of groundwater volume means that, rather than increasing over time, the groundwater concentrations of conservative compounds are controlled by concentrations in recharge sources such as effluent. The principal compounds that accumulate or persist in alluvial groundwater are those, such as strontium-90, that are not highly mobile. Strontium-90 has accumulated mainly in the canyon floor sediments, from which it slowly but continually leaches into the groundwater due to cation exchange, maintaining a nearly steady concentration. In some cases, such as RDV in Cañon de Valle, mobile contaminants also persist, possibly due to their continuing presence in water source regions.

A study by Purtymun et al. (1977) documented this rapid turnover of groundwater and solutes in Mortandad Canyon. Purtymun showed that the mass of various solutes in Mortandad Canyon alluvial groundwater was a fraction of the total solute mass that had been discharged into the canyon over the history of effluent releases. To a first approximation, the entire body of alluvial groundwater in Mortandad Canyon is chemically well mixed, and variations in concentrations of specific sources propagate throughout the groundwater system in times of about a year. Concentrations are at times higher for wells nearest to the outfall, partly because of variable mixing of effluent with ground and surface water. Concentrations appear to decrease downstream from the outfall due to mixing and the occasional higher values in upstream wells. While concentrations vary between wells, overall concentrations of the constituents are generally similar throughout the alluvial groundwater body at a given time.

Rather than a contaminant plume existing within the alluvial groundwater, a relatively small volume of groundwater (with a volume of about 20,000 cubic meters) is completely replenished annually by recharge water (with a volume of about 90,000 to 160,000 cubic meters) which includes the discharges from RLWTF at TA-50. Purtymun et al. (1977) attributed the losses of water to evapotranspiration and infiltration into the underlying tuff. The composition of the alluvial groundwater is a combination of input from the TA-50 facility and other sources such as

runoff and other Laboratory discharges. The groundwater composition nearest the TA-50 discharge point shows short term (weekly or daily) variations related to the TA-50 outfall, but over the longer term (annually), these variations are spread throughout the alluvial groundwater body.

Data for conservative constituents (tritium, nitrate) in alluvial groundwater support the conceptual model that this groundwater has a short residence time and conservative contaminants do not accumulate in alluvial groundwater. The time trend pattern for these contaminants shows a high level when they were being released, followed by a sharp decline in concentration to nearly nondetectable levels when the source is eliminated. Past values of tritium and nitrate in alluvial groundwater in DP, Los Alamos, Pueblo, and Mortandad Canyons exceeded the 20,000 pCi/L MCL (Rogers 1998). Such high values do not occur today in these locations because of improvement in effluent quality, and also possibly because of deeper infiltration of older effluents.

In Pueblo Canyon, tritium activity in alluvial groundwater was 15,000 pCi/L in the early 1970s, nearly a decade after effluent discharges ceased; today it is barely detectable (Figure 3-13). Similarly, alluvial groundwater tritium values in DP and Los Alamos Canyons exceeded 300,000 pCi/L in the late 1960s, but have been barely detectable for the past decade (Figure 3-14). TA-21 effluent caused tritium levels in surface water and alluvial groundwater in and downstream of DP Canyon to reach values up to 5,000,000 pCi/L, or 250 times the MCL (Figure 3-14, Figure 3-15). The tritium levels decreased greatly after discharges ceased. In Los Alamos Canyon above the mouth of DP Canyon, the Omega West Reactor cooling line leaked water containing tritium from 1956 to 1993. As a result of this leak, tritium activity in alluvial groundwater remained at values around 10,000 pCi/L or half of the MCL. Once the leak was discovered and shut off, tritium levels in Los Alamos Canyon water returned to background. In Mortandad Canyon alluvial groundwater tritium activities often exceeded 300,000 pCi/L and even reached 2,000,000 pCi/L, but have fallen below the MCL since the RLWTF adopted effluent limits in 2001 (Figure 3-15, Figure 3-16). At the end of 2000, the RLWTF adopted a voluntary goal of having tritium activity in its effluent below 20,000 pCi/L, and tritium activity in the effluent dropped below that in 2001 and was 10,400 pCi/L in 2003. Tritium activity in alluvial groundwater downgradient of the facility has dropped correspondingly, with a maximum value of 8,770 pCi/L in 2003.

Nitrate levels in Pueblo Canyon surface water and groundwater follow a strong downward trend similar to those for tritium. Nitrate has been discharged from Laboratory radioactive liquid waste effluents and Los Alamos County sanitary wastewater effluent (Figure 3-17, Figure 3-18). The highest values were found in surface water in the 1950s and 1960s, related to both types of sources. With decommissioning of the radioactive outfall in 1964 and moving the sanitary discharge downstream to the Bayo treatment plant, less water and less nitrate have been present in the upper portion of the drainage in recent years. Nitrate in discharges into DP Canyon from TA-21 caused surface water and alluvial groundwater concentrations to exceed 100 mg/L (nitrate as nitrogen), or 10 times the MCL, until discharges ceased in 1986 (Figure 3-18, Figure 3-19). Nitrate concentrations have returned to background since discharges ended. In Mortandad Canyon nitrate (as N) concentrations in alluvial groundwater have generally mirrored the concentration in RLWTF effluent (Figure 3-18, Figure 3-20). The nitrate concentration in the

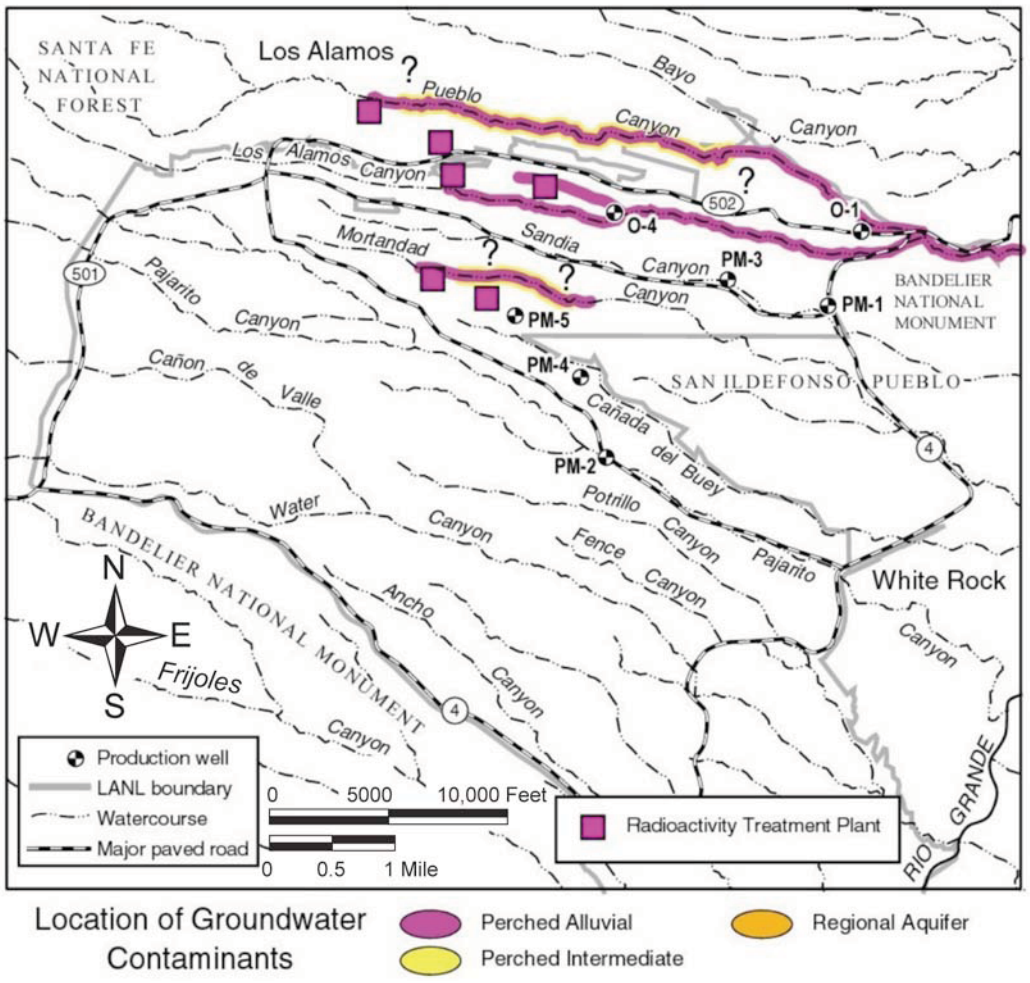

Figure 3-15. Location of inferred past extent of groundwater contamination by tritium above the 20,000 pCi/L EPA MCL. No groundwater tritium exceeded this value in 2003. Different colors indicate the affected groundwater zones. The extent of intermediate groundwater and regional aquifer contamination is based on a limited number of wells; question marks on the maps indicate where contaminant extent is inferred, not necessarily substantiated.

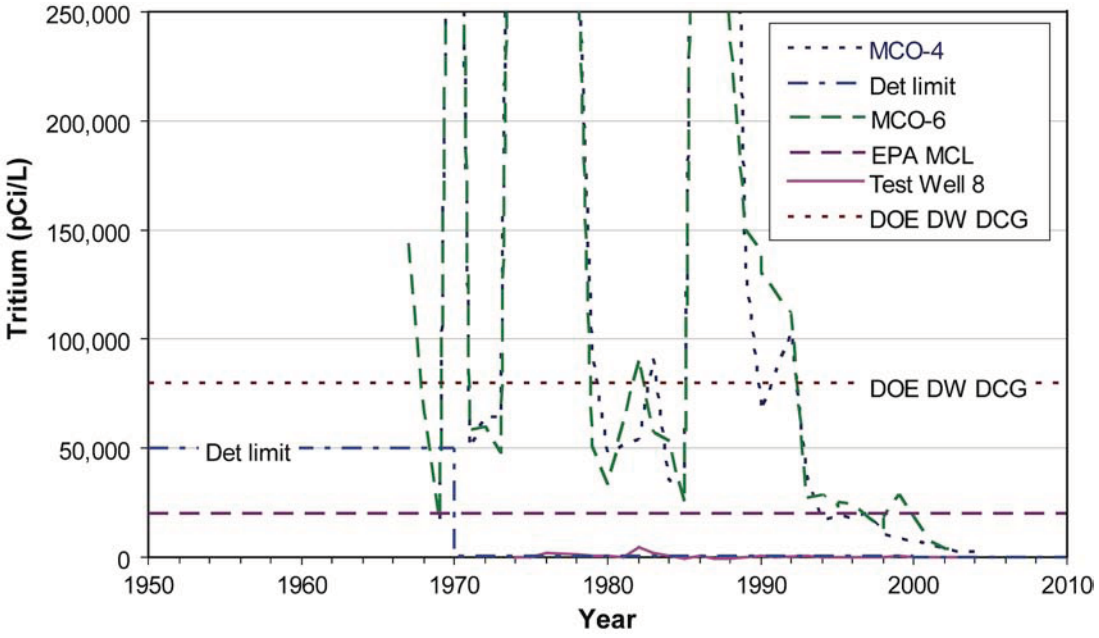

Figure 3-16. Tritium histories in Mortandad Canyon alluvial groundwater and the regional aquifer. Data are annual averages of all results including nondetects; note that detection limits have varied greatly through time.

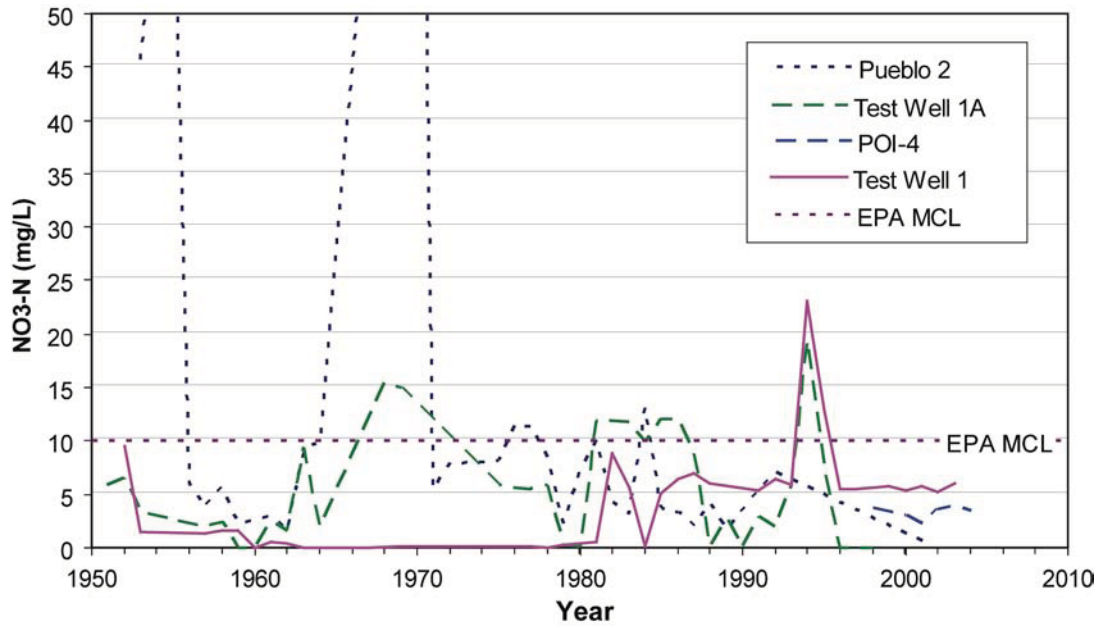

Figure 3-17. Nitrate histories in Pueblo Canyon surface water, alluvial and intermediate groundwater zones, and the regional aquifer. Data are annual averages of all results.

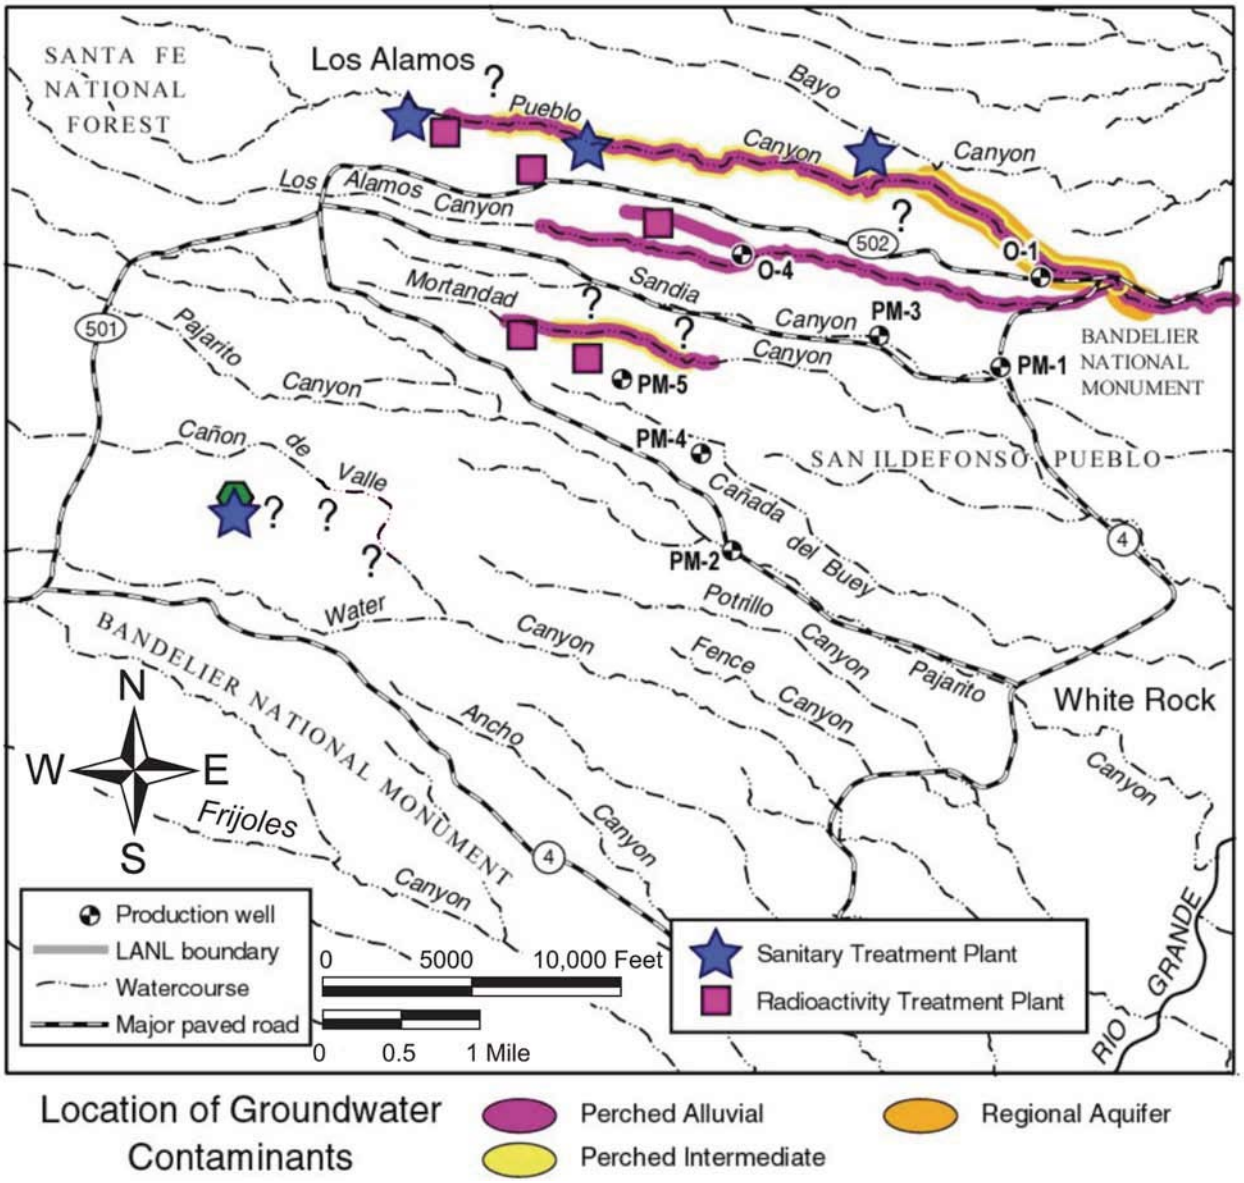

Figure 3-18. Location of inferred past extent of groundwater contamination by nitrate (as nitrogen) above the 10 mg/L EPA MCL. Only intermediate perched groundwater in Mortandad Canyon exceeded this level in recent years. Different colors indicate the affected groundwater zones. Along canyons, the extent of alluvial groundwater contamination lateral to the canyon is not to scale: contamination is confined to the alluvium within the canyon bottom and is narrow at the map scale. The extent of intermediate groundwater and regional aquifer contamination is based on a limited number of wells; question marks on the maps indicate where contaminant extent is inferred, not necessarily substantiated.

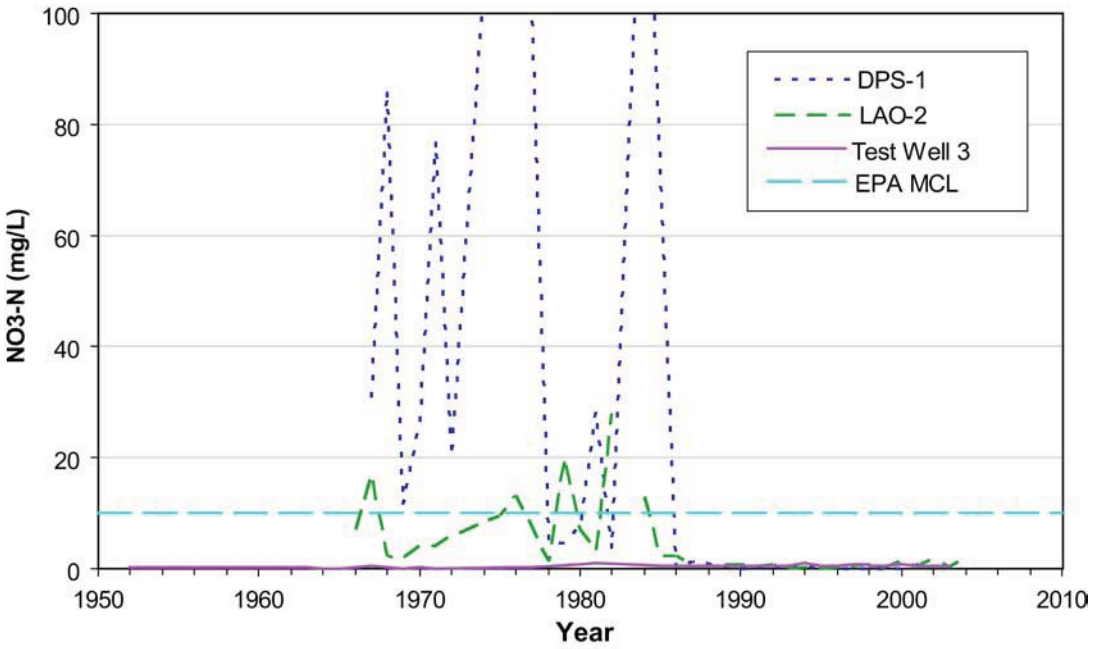

Figure 3-19. Nitrate histories in DP and Los Alamos Canyon surface water, alluvial groundwater, and the regional aquifer. Data are annual averages of all results.

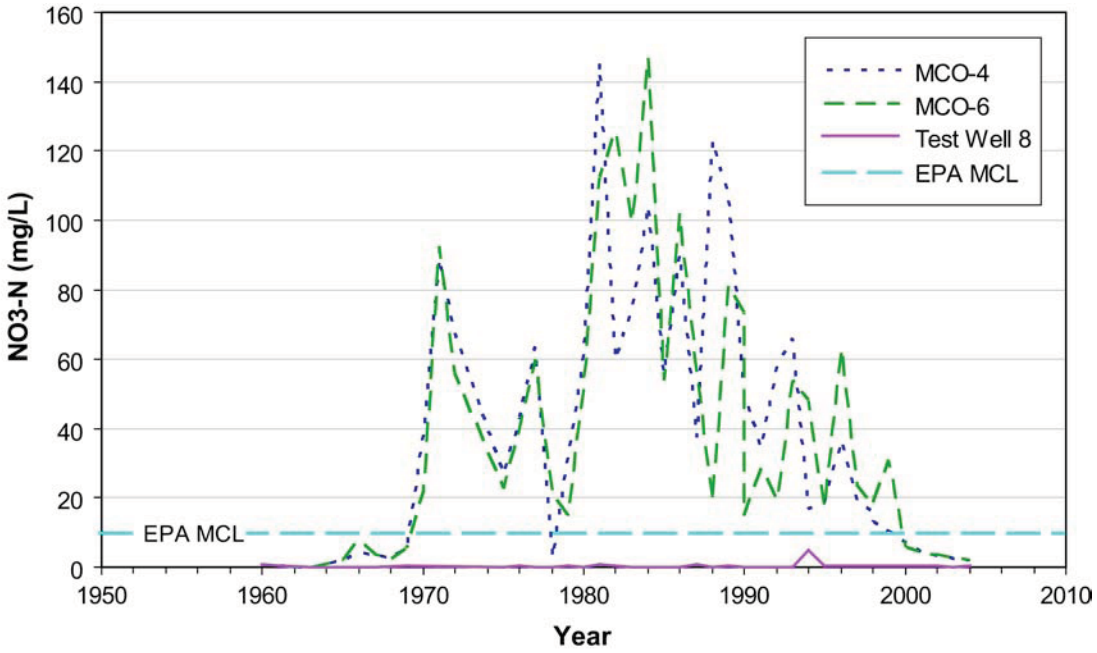

Figure 3-20. Nitrate histories in Mortandad Canyon alluvial groundwater and the regional aquifer. Data are annual averages of all results.

effluent decreased in 1999 due to improved treatment in the RLWTF, and alluvial groundwater concentrations have fallen below the New Mexico Groundwater Standard of 10 mg/L as a result.

The distribution of perchlorate indicates where effluent releases have occurred in canyons (Figure 3-21). Perchlorate history in Mortandad Canyon shows the rapid decrease in perchlorate after the source was eliminated (Figure 3-22). The perchlorate concentration in the effluent decreased in 2002 due to improved treatment in the RLWTF, and alluvial groundwater concentrations have fallen significantly as a result.

Data for adsorbing constituents (strontium-90, plutonium-239, -240) support the conceptual model of contaminant adsorption onto alluvial sediments. The adsorbing contaminants decline in concentration when the source is cut off, followed by maintenance of a fairly constant low concentration in the groundwater due to cation exchange. The highest measured strontium-90 activity was about 500 pCi/L in Acid Canyon surface water in 1960. With no present source, levels have dropped dramatically and strontium-90 is now seen only at low activities, below 1 pCi/L in alluvial groundwater (Figure 3-23).

In Los Alamos Canyon is strontium-90 contamination in surface water and alluvial groundwater derived from reactor sources at TA-2 and effluent discharges from TA-21 (Figure 3-24). The strontium-90 activity in DP Canyon surface water reached 28,600 pCi/L. There is no present source, and activities dropped greatly after discharges ceased. However, strontium-90 persists in alluvial groundwater at levels above the EPA MCL of 8 pCi/L due to the large inventory in alluvial sediment, which moves to the groundwater by cation exchange (Figure 3-24). Effects of Manhattan Project releases in upper Los Alamos Canyon cause plutonium-239, -240 activity in alluvial groundwater to remain at about 25% of the DOE 4 mrem drinking water derived concentration guide (DCG) of 1.2 pCi/L (Figure 3-25). Discharges from TA-21 resulted in plutonium-239, -240 activity in surface water much above the DOE 4 mrem DCG, even exceeding the 100 mrem DCG of 30 pCi/L in the late 1960s. Plutonium activity decreased substantially with the end of discharges in 1986, but is still occasionally detected in surface water and alluvial groundwater below the former outfall. In Mortandad Canyon the discharge from the RLWTF creates a localized area of alluvial groundwater where strontium-90 persists at levels above the 8-pCi/L EPA drinking-water MCL (Figure 3-26). The radionuclides plutonium-238; plutonium-239, -240; and americium-241 are also present above the 4-mrem DOE DCG for drinking water (Figure 3-27).

3.2.3.2 Vadose Zone Pathways and Transport in Intermediate Groundwater

A hydrogeologic control on movement of anthropogenic constituents through the vadose zone is the presence of geologic units that can act as pathways. In general, these are units that are conducive to perching groundwater and forming intermediate perched groundwater. The water quality impacts from effluent releases extend in a few cases to intermediate perched groundwater at depths of a few hundred feet beneath these canyons. Because the contaminated alluvial groundwater bodies are separated from the intermediate perched groundwater by hundreds of feet of dry rock, pathways within the vadose zone are likely present in those canyons.

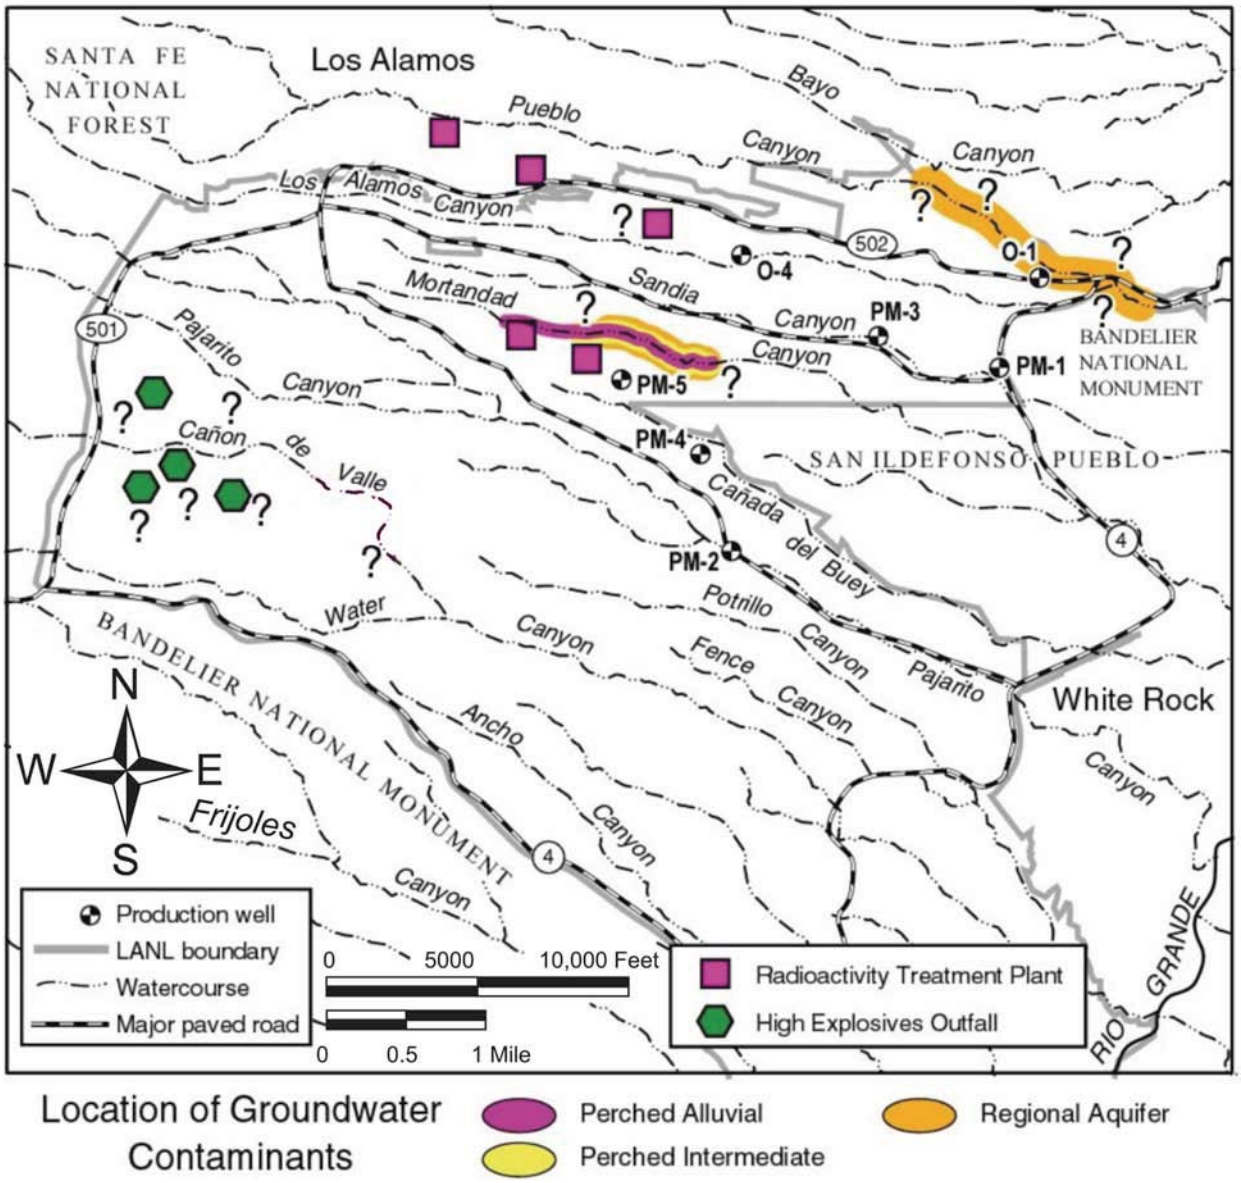

Figure 3-21. Location of groundwater contamination by perchlorate above the 3.7 ppb EPA Region VI risk level. Different colors indicate the affected groundwater zones. The extent of intermediate groundwater and regional aquifer contamination is based on a limited number of wells: question marks on the maps indicate where contaminant extent is inferred, not necessarily substantiated.

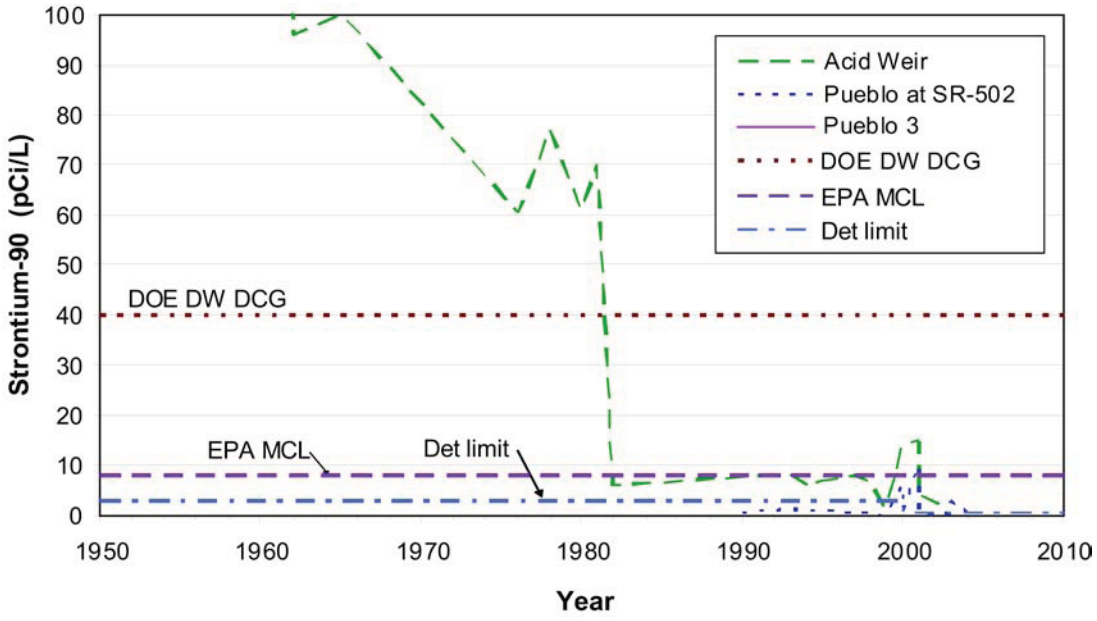

Figure 3-23. Strontium-90 histories in Acid and Pueblo Canyon surface water. The surface water data incorporate the longest record of strontium-90 and the highest values in these canyons; few strontium-90 detections have occurred in groundwater in these canyons. Data are annual averages of all results including nondetects; note that detection limits have varied greatly through time.

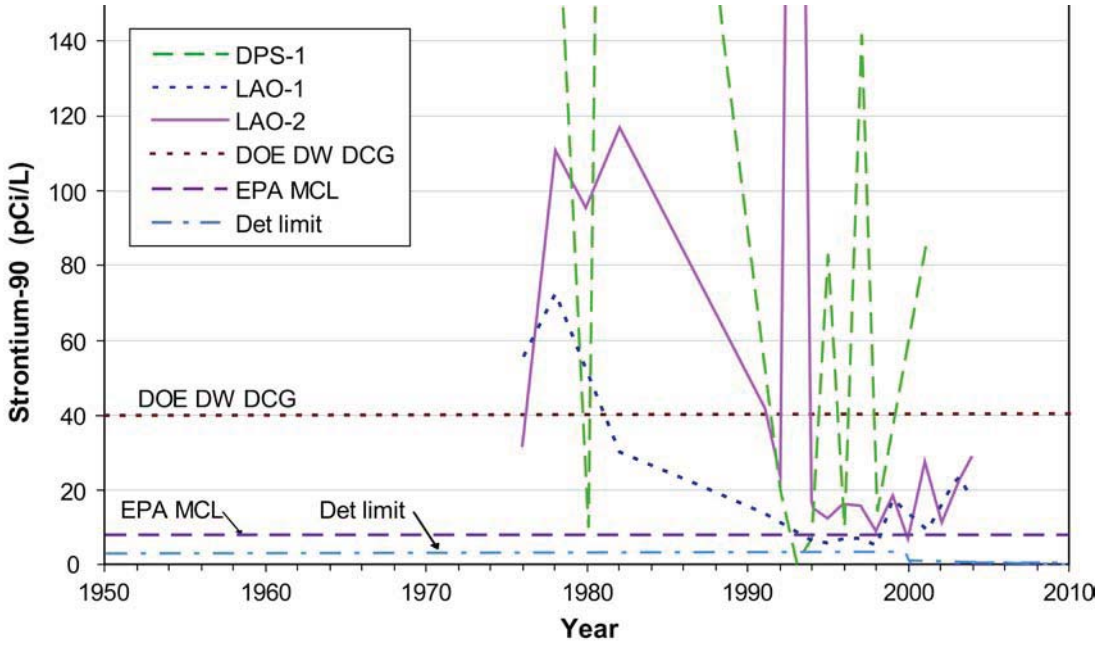

Figure 3-24. Strontium-90 histories in DP and Los Alamos Canyon surface water and alluvial groundwater. Data are annual averages of all results including nondetects; note that detection limits have varied greatly through time.

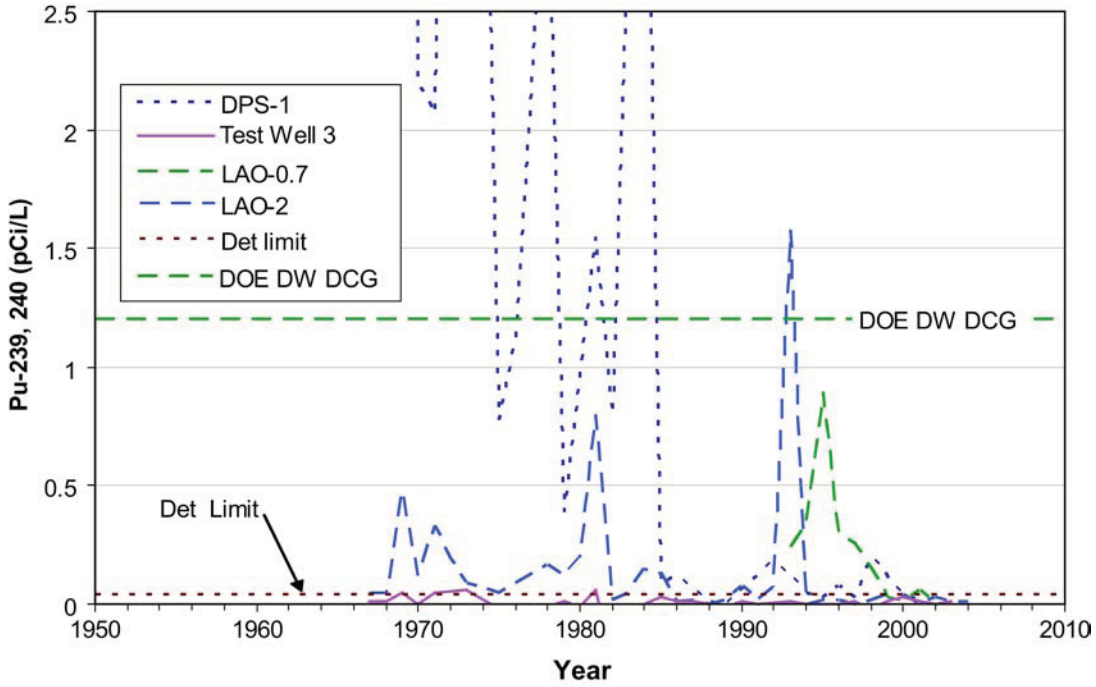

Figure 3-25. Plutonium-239, -240 histories in DP and Los Alamos Canyon surface water, alluvial groundwater, and the regional aquifer. Data are annual averages of all results including nondetects; note that detection limits have varied greatly through time.

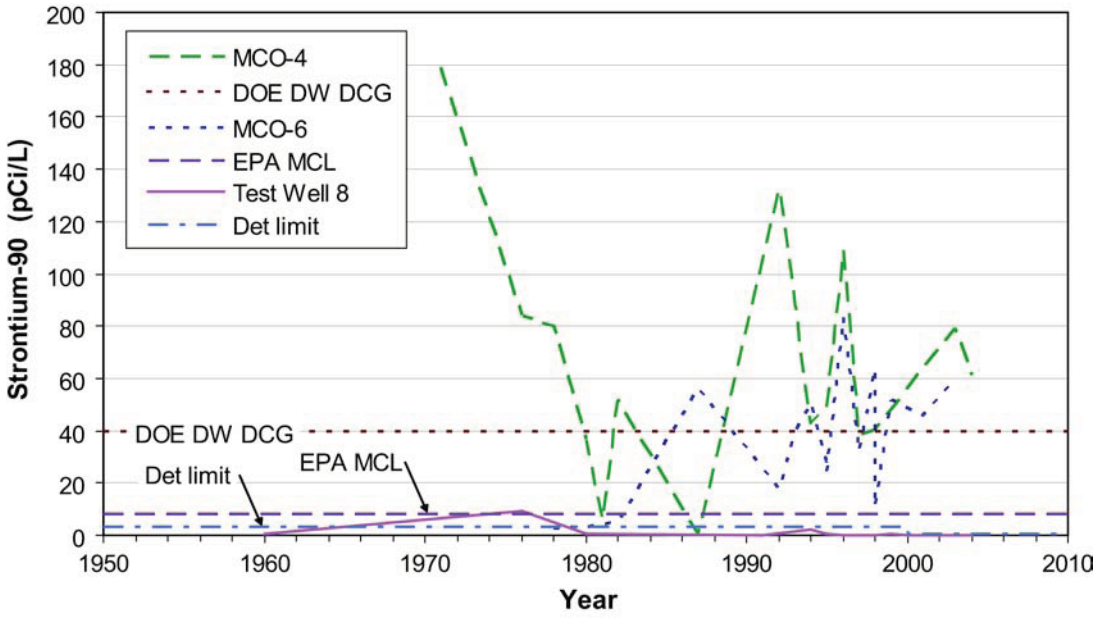

Figure 3-26. Strontium-90 histories in Mortandad Canyon alluvial groundwater and the regional aquifer. Data are annual averages of all results including nondetects; note that detection limits have varied greatly through time.

In Mortandad Canyon, Purtymun et al. (1977) estimated that, on average, about 15% of the surface water and shallow alluvial groundwater was lost to evapotranspiration. Because surface water or alluvial groundwater rarely flows beyond the Laboratory boundary, the remaining 85% of the water that enters the canyon must be lost by infiltration into the underlying tuff. Core profiles (Longmire 2001a) indicate a significant inventory of perchlorate and nitrate within the 400 ft of unsaturated Bandelier Tuff underlying the canyon floor.

Concentrations of contaminants such as nitrate, perchlorate, and tritium in Mortandad Canyon intermediate perched groundwater lie between current and past values in the alluvial groundwater. This banded range of observed concentrations suggests that the alluvial groundwater is a significant source of recharge to the intermediate groundwater; that this recharge requires on the order of decades; and that the solutes in the infiltrating water may be diluted by uncontaminated water already in the vadose zone or in the intermediate perched zone.

Low-level tritium data in intermediate perched groundwater support the conceptual model that alluvial groundwater affected by effluent discharges is a principal source of recharge and contaminants for the intermediate perched groundwater (Figure 3-28). The highest values are found where effluent discharges have occurred, but are much lower than values observed in alluvial groundwater. The lower values may be due to mixing of recharge with other groundwater sources as well as radioactive decay due to recharge time of decades. Higher-than-background tritium values occur in

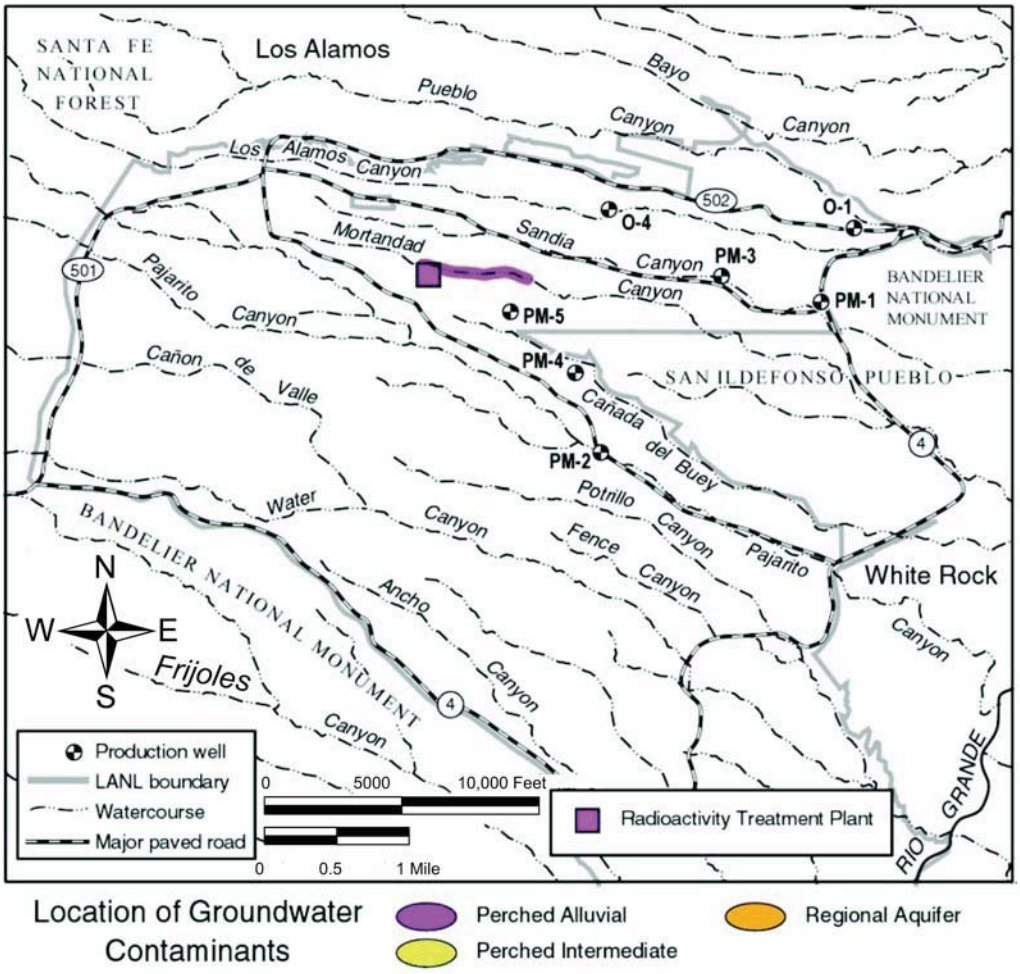

Figure 3-27. Location of groundwater contamination by plutonium-238; plutonium-239, -240; and americium-241 above the 4-mrem DOE DCG for drinking water. The 2003 maximum values in Mortandad Canyon alluvial groundwater for plutonium-238; plutonium-239, -240; and americium-241 were 1.4, 1.3, and 1.4 times the 4-mrem limit, respectively. Different colors indicate the affected groundwater zones.

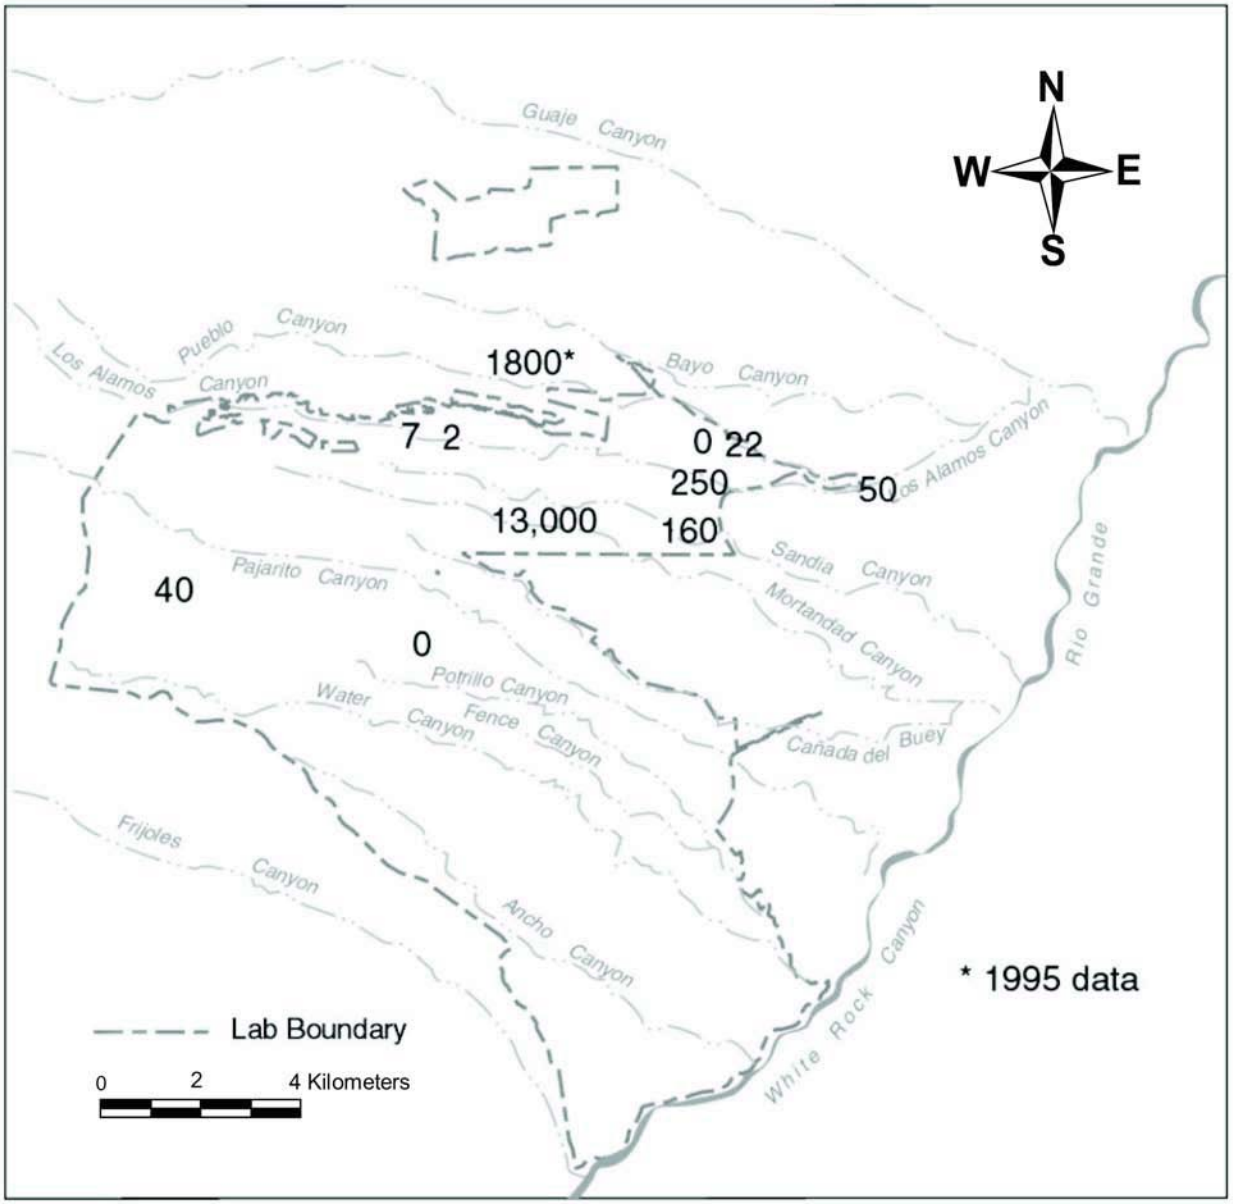

Figure 3-28. Low-detection-limit tritium data from wells and springs sampling intermediate perched groundwater. Data are mainly from 2002 to 2004 and do not include borehole data. The highest values occur where effluent discharges have occurred.

- R-25 near the 260 outfall and other discharges in TA-16,
- below the former TA-45 discharge in Pueblo Canyon,
- downstream from the Omega West reactor site and TA-21 discharges in Los Alamos Canyon, and
- below the sanitary effluent discharge site in Sandia Canyon, and the RLWTF in Mortandad Canyon.

Tritium time-series data also support a conceptual model that groundwater in the intermediate perched zones may have short residence times. Following cessation on effluent discharge from TA-45 into Acid Canyon in 1964, tritium in the intermediate perched zone sampled by TW-2A fell rapidly during the 1980s (Figure 3-13). Analysis of water samples from TW-2A show that this perched zone continues to contain elevated activities of tritium (2,228 pCi/L). This suggests that tritium associated with the former TA-45 treatment plant has infiltrated the canyon floor and migrated vertically, at least to the depth of the intermediate perched zone at TW-2A. Elsewhere in intermediate perched groundwater tritium has been detected mainly at trace levels (Figure 3-13). Although these incomplete data sets begin 15 years after discharges ceased, they support the conceptual model of short groundwater residence time.

In LADP-3 in Los Alamos Canyon, tritium activities fell rapidly over the decade after the Omega West reactor cooling line leak was stopped. Tritium was initially found in LADP-3 at 5500 pCi/L (Broxton et al. 1995) but activity has declined greatly since then, related to cessation of the Omega West reactor cooling line leak in 1993. Tritium in the two intermediate perched zones at R-9i was about 233 pCi/L at 180 ft and 110 pCi/L at 275 ft.

3.2.3.3 Flow Field Modification and Transport in Regional Aquifer Groundwater

Relatively little contamination reaches the regional aquifer from the alluvial groundwater bodies, and water quality impacts on the regional aquifer, though present, are low. The last hydrogeologic control, flow field modification, is considered important in controlling anthropogenic constituent distribution in the regional aquifer. Anthropogenic constituents that enter the regional aquifer near pumping wells are predicted to have much travel times than those outside the influence of pumping (Section 4).

The distribution of tritium in the regional aquifer supports the conceptual model that surface effluent discharges are the source of Laboratory contaminants at depth (Figure 3-29). The map shows low-level tritium values from 2002-2004 and includes springs and wells.

In most cases, the highest regional aquifer tritium values are found near where effluent discharges have occurred, but are much lower than values observed in overlying alluvial or intermediate perched groundwater. The lower regional aquifer values may be due to dilution of recharge by other groundwater sources as well as radioactive decay due to recharge times of decades. The locations of the highest values in Figure 3-29 are near the recharge sources described in Appendix 3-A, with two additional locations that have high tritium values. One is at R-22 near MDA G, which may be due to past tritium disposal at that site. The second is at

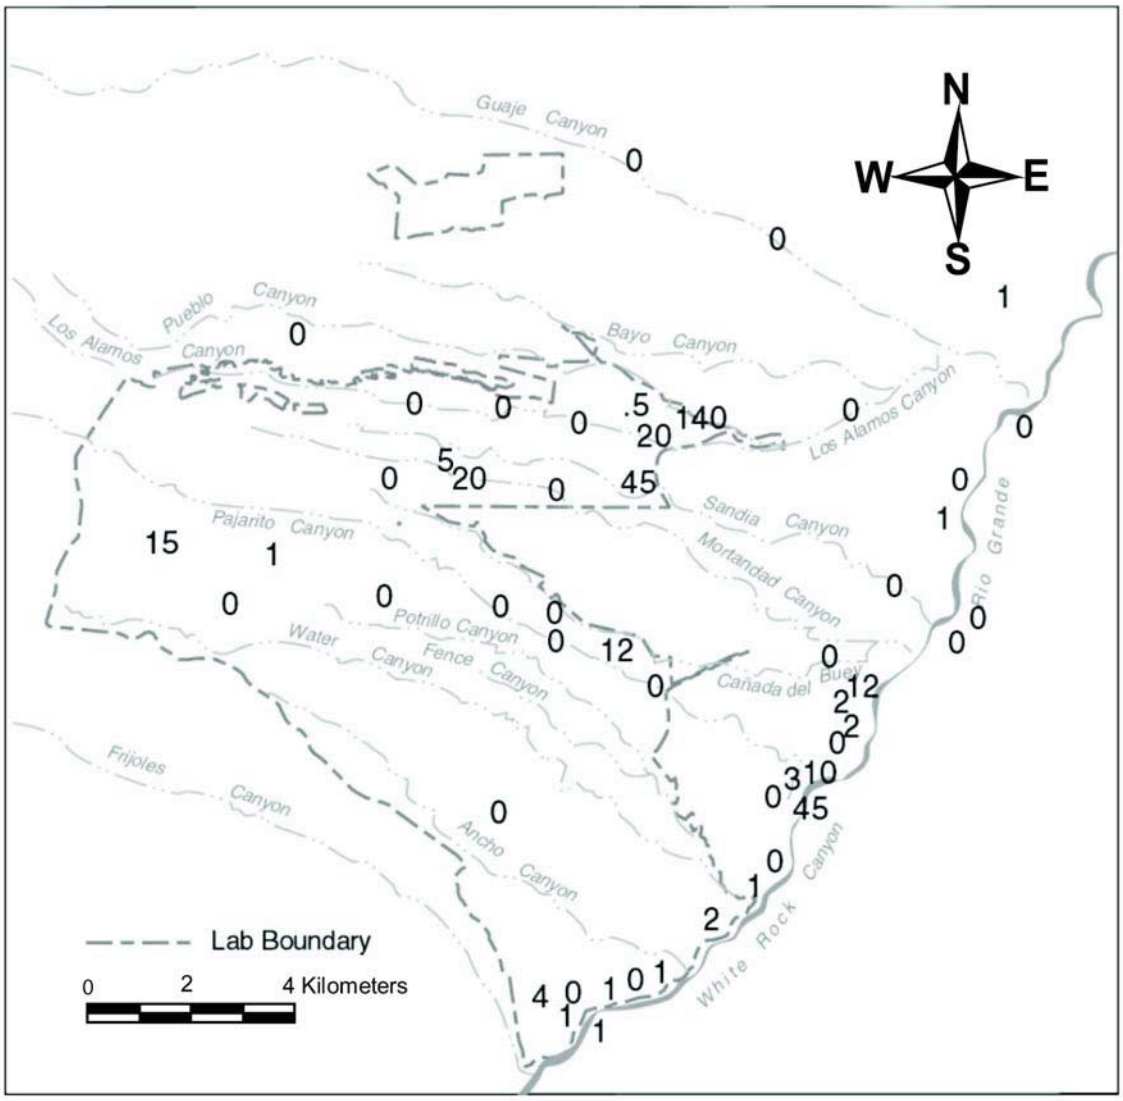

Figure 3-29. Low-detection-limit tritium data from wells and springs sampling the regional aquifer. Data are from 2002 to 2004 and do not include borehole data. The highest values occur where effluent discharges have occurred.

Spring 4B. The values, in the range of 45 pCi/L, are similar to data from rainfall and the Rio Grande and may be due to a component of surface water in the spring sample (LANL 2004b).

3.2.4 Off-Site Transport

Anthropogenic constituents that reach the regional aquifer will be transported along flow paths that will extend either to pumping wells or to the Rio Grande, the discharge area for the regional aquifer in the Española Basin (Section 2). The travel times along the natural flow paths are quite long (tens of thousands of years), but can be shorter for flow paths leading to pumping wells (Section 4).

As discussed in Section 3.2.1, the most mobile contaminants would be the first to appear in any of the regional aquifer discharge points. Appendix 3-A contains descriptions of canyons and the constituents that have been detected in the regional aquifer. Highly mobile groundwater contaminants including chloride, nitrate, perchlorate, and tritium have migrated into the regional aquifer near LANL. Monitoring data suggest that these constituents may also be discharging in some White Rock Canyon springs. Nitrate, chloride, and sulfate have increased gradually during the past 20 years in Spring 3 and Spring 3A (Figure 3-30). Tritium values in the springs are either in the range of regional aquifer values (less than 3 pCi/L) or up to 45 pCi/L, which could indicate either Laboratory impact or a component of precipitation (tritium in precipitation is 30–450 pCi/L). Perchlorate measured at low levels in some springs appears to be naturally occurring because it is within the range of regional background levels.

Four alternative pathways have been articulated to explain the presence of anthropogenic constituents in White Rock Canyon springs. One potential source is effluent discharged from the county's sewage treatment plants. McQuillan et al. (2004) noted that Los Alamos County water supply well Otowi-1 produces water with above-background nitrate, and detectable perchlorate and tritium, as do some of the springs. The calcium-bicarbonate groundwater at Spring 2B is chemically similar to that in regional aquifer well TW-1 in lower Pueblo Canyon. Although the Spring 2B major ion chemistry is consistent with the upgradient geochemical data from TW-1 in lower Pueblo Canyon, TW-1 is located approximately 4 miles away from Spring 2B. The White Rock Sewage Treatment Plant is very close to the springs. Both TW-1 and Spring 2B are located near (separate) municipal sewage discharges and the common sewage signature could yield similar water chemistries at both sites. Nitrate and chloride are common contaminants associated with sewage effluent.

McQuillan et al. (2004) suggest rapid transport in the regional aquifer from Pueblo Canyon to White Rock Canyon. Contaminants released in Acid Canyon, after having reached the regional aquifer, traveled rapidly through the regional aquifer in an easterly, then southerly path line starting at about Otowi-1 and TW-1, discharging in several springs along White Rock Canyon. However, these flow paths are inconsistent with the gradients in the regional aquifer, based on the latest potentiometric data. This pathway also requires rapid transport through the regional aquifer, contrary to evidence (carbon-14 data) that suggests slow transport through the regional aquifer (Sections 2.7.7 and 4). Water from lower Pueblo Canyon would need to travel many miles through the regional aquifer to Spring 2B with minimal mixing or dispersion in order to account for the observed concentrations.

One further geochemical argument, which suggests that water in Spring 2B does not originate near O-1 and TW-1 in Pueblo Canyon, is the high uranium concentration in Spring 2B water. Uranium concentrations in Spring 2B are sharply anomalous compared to adjacent springs. There have been no high uranium concentrations measured in regional groundwater beneath LANL or Pueblo Canyon (Gallaher et al. 2004) that are comparable to those in Spring 2B. However, high natural uranium concentrations are known to exist throughout the Pojoaque Valley, in the well field in lower LA Canyon, and in the nearby Buckman wellfield. The natural levels have been shown to vary in response to pumping in the old LA wellfield, and delayed impacts may appear in Springs 1 and 2.

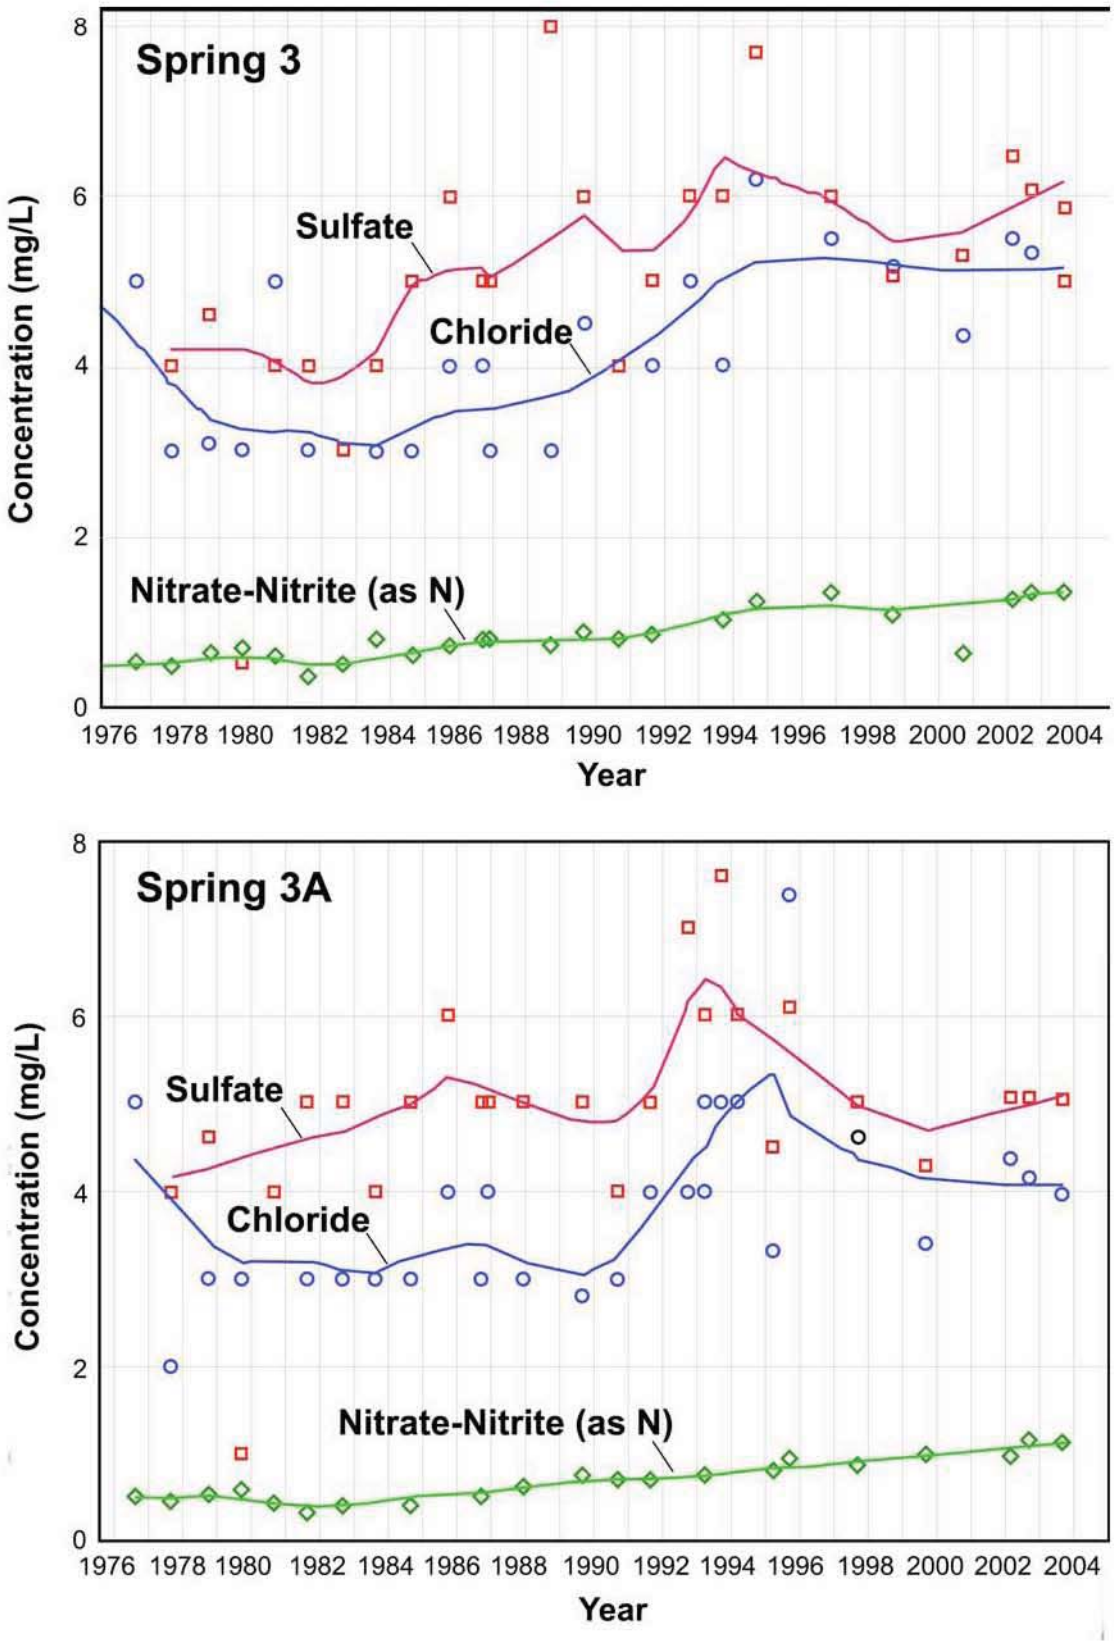

Figure 3-30. Anion concentrations in Springs 3 and 3A. Solid lines are best fit smooths to the data using loess methods (Cleveland 1979).

A second hypothesized pathway is a local source for contaminants present in the springs. Spring 2B chemistry is consistent with effluent from the White Rock Sewage Treatment Plant (located on the White Rock Canyon rim above Spring 2B). The decades-long increases in nitrate and chloride concentrations in Springs 3 and 3A suggest a sustained source such as an effluent discharge. Surface flows from the plant pass near these springs.

The third potential pathway is near-surface transport of contaminants to the White Rock Canyon springs. LANL contaminants are hypothesized as being transported in surface water and/or shallow groundwater along Pajarito Canyon from TA-9 to White Rock, followed by infiltration near the springs and a relatively short transit through the vadose zone to the regional aquifer. Such fast, shallow paths are more plausible and consistent with available information than fast transport through the regional aquifer. The major ion chemistry in the springs near Pajarito Canyon is generally consistent with that of groundwater along this flow path. Some fast regional aquifer transport would still need to occur for the contaminants to reach the springs.

The fourth possible pathway is transport via alluvial groundwater and fractural basalt. This pathway involves Laboratory contaminants reaching the springs via shallow and deep pathways in which transport is dominated by movement through fractural basalts. Fast transport through the basalts is more plausible than fast transport in the regional aquifer within the Puye Formation or the Santa Fe Group. The basalt-dominated pathway would likely be fast through the vadose zone as well. Drilling to date has not located any major contamination zones in basalt, but such zones could be isolated and difficult to encounter.

If any of the hypothesized alternative fast pathways invoked to explain the possible presence of LANL-derived constituents in springs exist, groundwater beneath LANL may travel more rapidly to downstream wells or springs than previously recognized, but the overall water quality changes would be anticipated to be relatively minor. Faster travel in the regional aquifer likely would result in less natural attenuation (for example, adsorption, radioactive decay, mixing) of any LANL-derived contamination. The monitoring history to date, however, has revealed minor impacts on the regional aquifer beneath the Laboratory. Continued LANL-wide groundwater monitoring is the most effective mechanism for identifying potential off-site transport of contaminants. See Appendix 3-D for discussion of other alternative conceptual transport models.

3.2.5 Summary of Contaminant Distribution and Transport

The impacts to groundwater at the Laboratory have occurred mainly where effluent discharges have increased local infiltration rates and volumes. The depth to which chemical constituents move in the subsurface is determined partly by their chemical behavior: non-reactive constituents move readily with groundwater, while reactive or adsorbing constituents move a shorter distance.

In most cases where effluent sources have been eliminated, groundwater concentrations of non-reactive discharged contaminants have decreased far below past levels (e.g., RDX, nitrate, tritium, and perchlorate) in alluvial groundwater. These mobile contaminants readily move through the subsurface and are detected within perched intermediate zones and at the regional water table beneath several canyons, including Pueblo Canyon, Los Alamos Canyon, Sandia

Canyon, Mortandad Canyon, and Cañon de Valle. In the case of reactive or adsorbing chemicals, the concentrations may remain elevated above background levels for long periods of time after elimination of discharges or other contaminant source terms (e.g., excavation and removal of contaminated sediments). These include constituents such as strontium-90 and the actinides (americium-241, plutonium-238, and plutonium-239, -240).

4.0 NUMERICAL MODELS

The conceptual models of the hydrogeologic system beneath the Pajarito Plateau, as well as the supporting data and information, were described in Sections 2 and 3. Numerical modeling is an analytical tool that can be used to integrate and synthesize the sometimes widely spaced point hydrogeologic field data and that allows prediction of how the hydrologic system will behave at different times and under different conditions in the future. However, before models can be used for prediction, they must be shown to adequately reproduce current conditions. A caveat is that different model representations (assumptions, boundary conditions, structural features, dimensionality) can in many cases provide equally good fits to available data. This fact, sometimes called equifinality in the hydrologic literature, implies that different model representations may result in significantly different model predictions. In this section we have selected representative model structures that are most consistent with the available information, while acknowledging that conceptual uncertainties also exist. This section describes the site-scale vadose zone and regional aquifer models that have been developed, including the underlying assumptions, hydrologic processes, calibration, and predictions for flow and transport.

4.1 Site-Wide Vadose Zone Flow and Transport Model

Hydrologic modeling of the vadose zone has been conducted to understand the key factors influencing the transport of contaminants from the ground surface to the regional aquifer, and to quantify uncertainties. The main goal of the site-wide vadose zone flow and transport model is to identify regions at the Laboratory where deep migration of contaminants is most likely. These analyses have been useful for guiding and prioritizing site characterization activities and can be used to support risk and performance assessments.

The following summary describes the underlying assumptions and hydrologic processes, and presents numerical modeling predictions of the travel times from the ground surface to the top of the regional aquifer across the Pajarito Plateau. Simulation of travel time of traced water is a necessary first step in predicting the velocities and concentrations of contaminants through the vadose zone. For a modeling analysis that includes predictions of tritium concentrations, see the presentation of a numerical model for Los Alamos Canyon in Section 4.1.3.2.

4.1.1 Model Development

Transport of water and dissolved chemicals through the vadose zone beneath the Pajarito Plateau has been the subject of numerous laboratory and field investigations and numerical model development efforts. The characterization and modeling of vadose zone systems requires knowledge of the water supply, percolation rates and the hydrologic properties of rocks and soils under unsaturated conditions. Such an understanding, at a basic level, has been acquired for the Bandelier Tuff underlying much of the Pajarito Plateau. In the past, that knowledge has been used to develop geometrically complex numerical models to investigate in detail the influence of dipping stratigraphy, rugged topography, and manmade alterations to the natural system (see Section 4.1.3 for examples).

Due to the complexity and computational demands of vadose zone models, they typically cover only a small portion of the Laboratory property, and thereby provide only a local picture of the vadose zone system. This section describes a site-wide model for performing first-order analysis of travel time through the vadose zone across the entire Pajarito Plateau. By foregoing some of the complexities in favor of a simpler representation of the flow physics, this model can be extended to include all locations of interest on the LANL property.

The following subsections present the modeling inputs, assumptions, and methodology in more detail.

4.1.1.1 Flow and Transport Processes

Despite the potential complexities associated with vadose zone systems, many basic processes are amenable to characterization and numerical simulation. In the Bandelier Tuff, when the percolation rate is lower than the saturated hydraulic conductivity K_{sat} of the matrix rock, the fluid saturation in the partially water-filled pores modulates itself in order to transmit the fluid under unit-gradient conditions associated with gravity-driven flow. Section 2.6.3 included data suggesting that under most conditions, water percolates through the Bandelier Tuff matrix, and the role of fractures is minor, except for the uppermost units of the Tshirege Member, present only in the westernmost portion of the Laboratory. In these locations, units with very low hydraulic conductivity induce lateral flow, probably through fractures. This phenomenon leads to shallow zones of saturation in which water travels laterally and issues at springs in Cañon de Valle and Water Canyon, from which it flows vertically downward through the rest of the Bandelier Tuff in matrix flow. In contrast, flow through the basaltic and dacitic rocks is assumed to be controlled by fractures. The practical consequence of these conceptual models for travel times will be established in the numerical modeling results. Finally, flow through the Puye Formation is probably also matrix-dominated, although the hydrogeology is complicated and the possibility of channelized, heterogeneous flow must be considered.

In spite of the inherently three-dimensional nature of flow in the vadose zone, an appropriate approximation for estimating travel time is to assume one-dimensional downward percolation of water and migration of contaminants. Intermediate perched groundwater observed in several wells across the Plateau indicates the possibility of lateral diversion (see Section 2.7), but the influence of such groundwater on vadose zone travel time can be assessed in a bounding manner, as is illustrated in Section 4.1.2.3.

4.1.1.2 Infiltration Rate

As the upper fluid flow boundary condition, infiltration is one of the most important inputs for a vadose-zone model. Infiltration is known to depend, often in a complex way, on the local surface hydrologic conditions, topography, microclimatic conditions, evapotranspirative (ET) conditions (including vegetation type), and the presence or absence of impermeable layers such as thin clay layers within and at the base of the alluvium. The water that escapes ET and surface runoff is assumed to percolate through the remainder of the vadose zone to the regional aquifer, carrying with it any aqueous chemicals such as contaminants or dissolved minerals. The percolation rate below the zone of evapotranspiration is the direct input to the vadose zone numerical models. Although this rate undoubtedly changes with time due to storm transients, seasonal variations, and climatic variability, it is assumed that such effects are buffered by the hydrologic processes

that redistribute water in the surface water, alluvial groundwater, and unsaturated rocks of the vadose zone, so that an equivalent constant percolation rate can be assigned. The infiltration rate is also spatially variable at scales ranging from the width of fractured zones to the length of individual canyons.

The methodology for estimating infiltration rates across the Pajarito Plateau is to classify canyons or portions of canyons with a numerical designator, called the Net Infiltration Index (NII). Then, for applying infiltration in the numerical model, each NII would have associated with it an infiltration rate. For the mesas, a uniform infiltration rate of 1 mm/yr was assumed. Appendix 4-A presents the development of the NII values across the Pajarito Plateau; the results are depicted in Figure 4-A-1. Table 4-1 lists, for each NII, the descriptive characteristics of each infiltration class, and the infiltration rates associated with each of the model runs.

4.1.1.3 Numerical Model Implementation

To predict travel time, the FEHM computer code (Zyvoloski et al. 1997) was used to simulate the two-phase, air-water flow problem. For the vertical stratigraphy predicted by the site geologic model, a one-dimensional grid was constructed with 10 evenly spaced numerical grid points within each layer. Hydrologic properties of each unit were assigned based on laboratory measurements and results of previous vadose-zone modeling efforts, and the percolation rate was assigned based on the infiltration map (Figure 2-34). The calculation consists of two steps: first, a steady-state one-dimensional fluid flow calculation is executed to establish the fluid water contents and water velocities through the stratigraphic column from the surface to the water table. Then, this steady-state flow model is used to compute a travel time using particle tracking. After performing the calculation at numerous locations across the Plateau, a site-wide description of vadose zone travel times is assembled in the form of travel-time maps.

To conduct these calculations, several steps of the process were automated within a GIS-based data assembly and querying system. At a given location, the one-dimensional vertical stratigraphy from the site-scale geologic model was used to generate a numerical grid for flow and transport calculations. The point distribution for the one-dimensional models consisted of a high density of points close to drainages across the Pajarito Plateau, and a coarser resolution on the mesas. Regions corresponding to the drainages, where relatively large infiltration is applied, were converted to a high-resolution grid (cell size of 128 ft) with each point located in the center of the cell. On the mesas, a coarser point distribution of 512 ft was taken. This resulted in a total of 30,577 points across the plateau at which one-dimensional transport times were calculated.

Table 4-1.
Determination of Net Infiltration Index and Net Infiltration Rates Used in the Model

Net Infiltration Index (NII)	Headwaters or Source	Surface Water	Alluvial Water	Net Infiltration Estimate (mm/yr)	
				Base Case	High Infiltration Scenario
1	Plateau	Ephemeral or Intermittent	Not Saturated	1	10
2	Mountain or Small Anthropogenic Source	Ephemeral or Intermittent	Not Saturated	10	30
2	Plateau	Ephemeral or Intermittent	Sometimes Saturated	10	30
2	Plateau	Perennial	Not Saturated	10	30
3	Plateau or Small Anthropogenic Source	Ephemeral or Intermittent	Saturated	100	300
3	Mountain	Ephemeral or Intermittent	Sometimes Saturated	100	300
4	Plateau	Perennial	Saturated	300	1000
4	Mountain or Anthropogenic Source	Ephemeral or Intermittent	Saturated	300	1000
5	Mountain or Large Anthropogenic Source	Perennial	Saturated	1000	3000

4.1.2 Model Results

Numerical modeling results are presented for a "base-case" model for canyons and mesas, after which uncertainty in infiltration rate and the impact of perched water conceptual uncertainty are studied.

4.1.2.1 Base-Case Results

A full-scale map of predicted travel times of a water molecule in the vadose zone (from ground surface to the water table of the regional aquifer) is shown in Figure 4-1. Along each canyon with NII other than 1, travel times are predicted to be less than 1000 years. Although the results in canyons are the main focus of this study, results for the mesas are described first. On mesas, the predicted travel times are variable, but for the most part are greater than 1000 years, ranging from 1000-5000 years on the eastern portions of the Laboratory to 20,000 to 30,000 years in the western region.

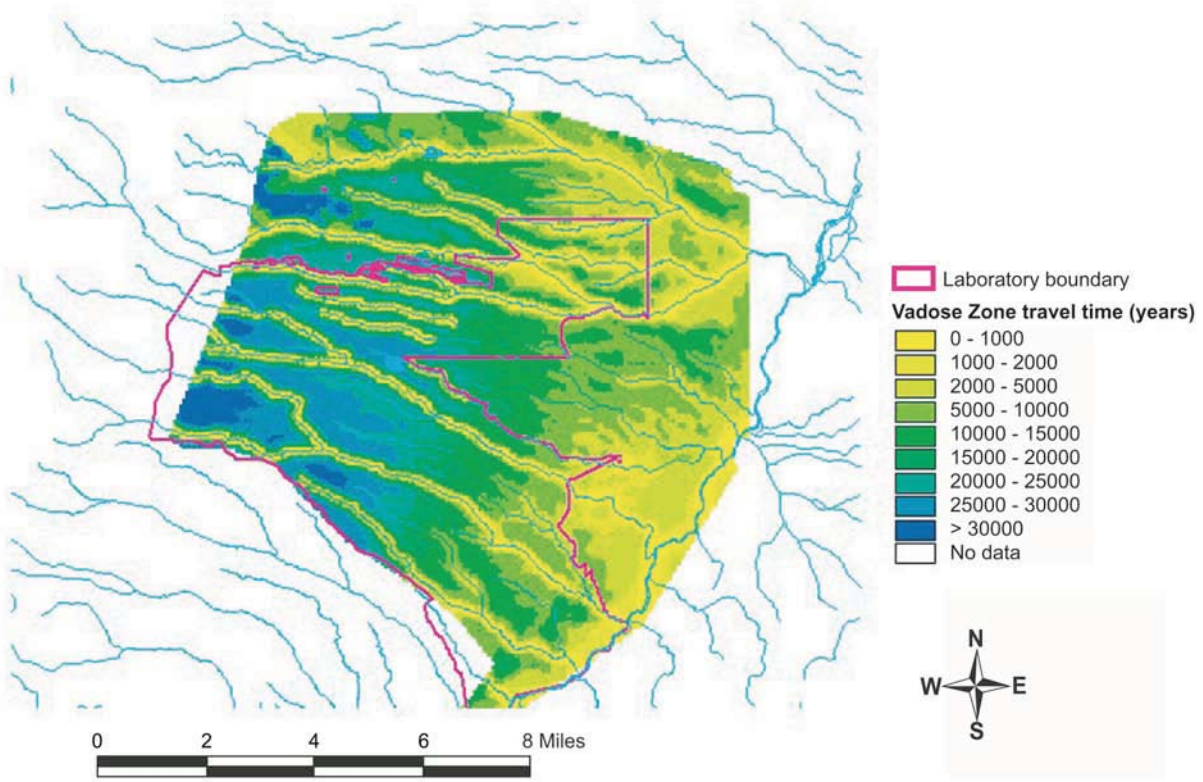

Figure 4-1. Predicted vadose zone travel times (years) to the water table: Base case, full scale of travel times.

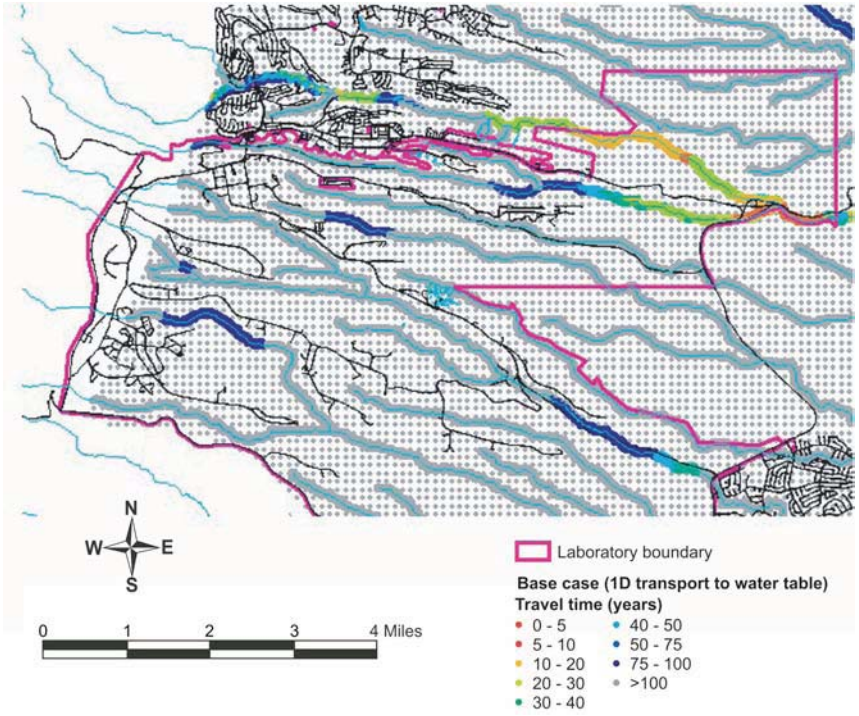
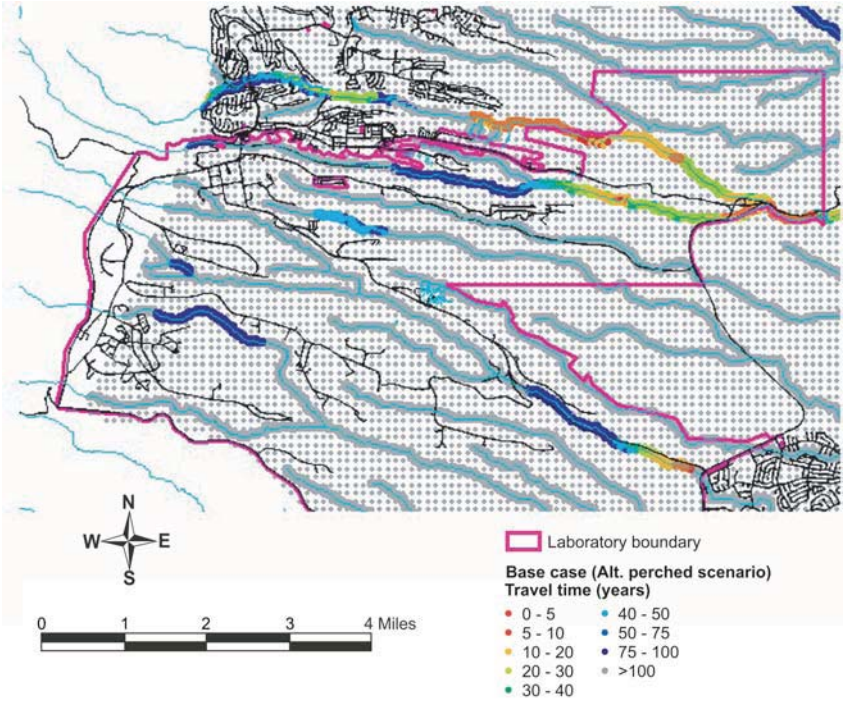
To a first approximation, travel times from mesa tops are controlled by the thickness of the Bandelier Tuff. Because the Bandelier Tuff exhibits matrix percolation, the travel times on the mesas are controlled by slow percolation at a flux of 1 mm/yr through these units. Other units between the ground surface and the water table are the Cerros del Rio basalts, the Puye Formation, and the Tshicoma dacites. The basalts and dacites are modeled with an extremely low porosity (0.01) to capture the conceptual model feature of flow through these units controlled by fast pathways such as fractures or other heterogeneities. Therefore, most of the travel time to the water table is within the Bandelier Tuff, and the travel time map is therefore dominated by the tuff thickness.



Identification of rapid travel times to the water table from canyon bottoms is important to determine if they are in locations likely to have experienced Laboratory-derived groundwater contamination. Figure 4-2a shows the base-case model result presented in Figure 4-1, except that the travel-time scale ranges from 0 to 100 years (all points with values greater than 100 years are shown in gray). The model predicts that regions of relatively rapid travel times are present in the following canyons: Pajarito Canyon near White Rock, a portion of Cañon de Valle, Mortandad Canyon at the Radioactive Liquid Waste Treatment facility, middle and lower Los Alamos Canyon, large portions of Pueblo Canyon, and Guaje Canyon.

Two factors control these results: infiltration rate and hydrostratigraphy. Generally, travel times less than 100 years are predicted in the portions of canyons with NII values of 4 or 5 (300 mm/yr and 1000 mm/yr, respectively), especially in locations where the Bandelier Tuff is thin. Clearly, canyons with high infiltration rates are locations in which travel times through the vadose zone are likely to be relatively short. In addition, Los Alamos and Pueblo Canyons have regions in the vicinity of their confluence in which the Bandelier Tuff is thin or non-existent. Water infiltrates directly onto basaltic rocks or the Puye Formation, thereby yielding rapidly downward flow through fractures or preferential flow channels. The predicted travel times are especially short (5 to 10 years) in these locations.



4.1.2.2 Uncertain Infiltration Rate

The infiltration rates associated with the NII are uncertain, and therefore must be varied to investigate the uncertainty in the model predictions. Figure 4-3a shows the same vadose zone travel time map as in Figure 4-2a, but for the high infiltration rate scenario (NII = 4-5). As expected, travel times are shorter at the same location in any particular canyon at the higher infiltration rate. As a result, greater stretches of canyons are predicted to exhibit travel times to the regional aquifer water table of less than 100 years. Specifically, in the high flux scenario, most of Pajarito Canyon, much longer stretches of Mortandad and Los Alamos Canyons, Cañon de Valle/Water Canyons from the west to the central portion of the Laboratory, and all of Pueblo Canyon in the vicinity of the Laboratory are predicted to have travel times that are less than 100 years.

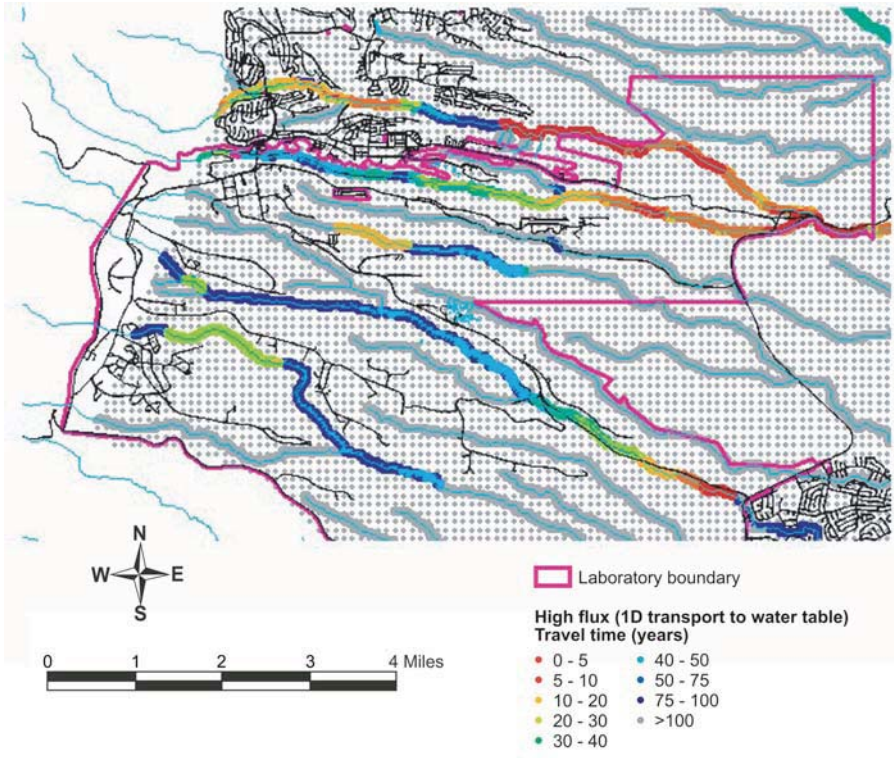
This analysis highlights a key uncertainty in the model: the lack of precision in predicting the percolation rate from canyon bottoms. Because contaminants have been introduced into the groundwater in canyons, it is likely that the percolation rate will be one of the key uncertainties that detailed site characterization may address, possibly in conjunction with sensitivity analyses.

(a)

(b)

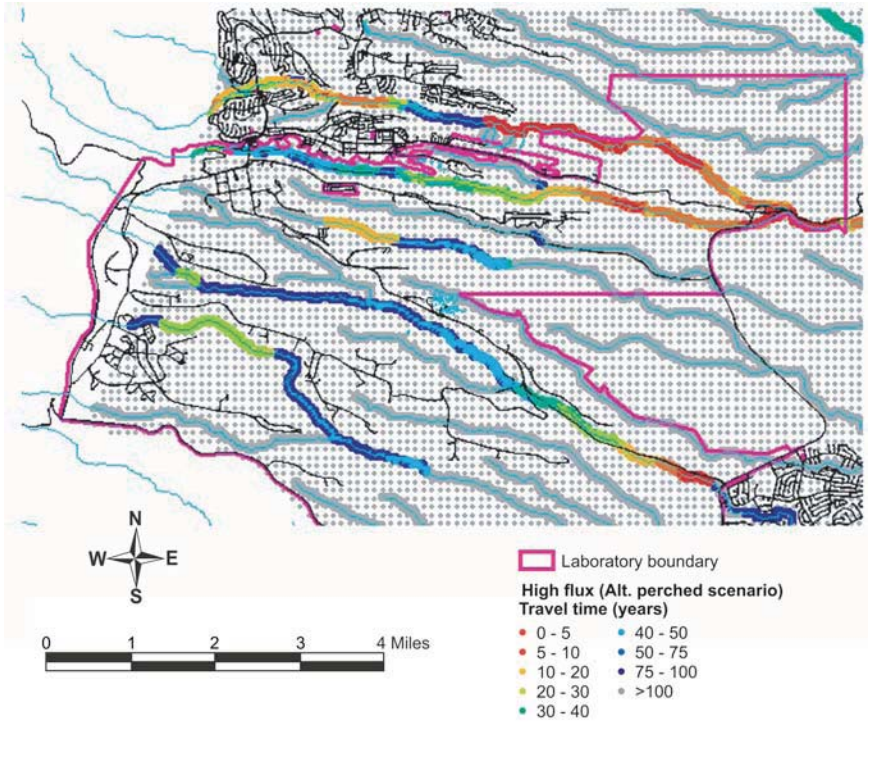
Figure 4-2. Predicted vadose zone travel times (years) to the water table, showing only travel times of 100 years or less. Base case percolation scenario: (a) 1-D transport to the water table; (b) alternate perched water model.

4.1.2.3 Perched Water Conceptual Uncertainty



The one-dimensional, vertical transport model assumption is an approximation that may not be valid, given the presence of intermediate groundwater at various locations around the Laboratory. As presented in Section 2.7, zones of saturation have been located directly beneath canyons, where infiltration rates are highest. There is little or no evidence that connected groundwater pathways exist over large areal distances beneath mesas. Given the limitations of the data, the approach taken in the present study is to bracket the range of travel times to the water table that would be predicted assuming "end-member" conceptual models for perched water discussed in Section 2.7:

- Low velocity, virtually stagnant fluid
- High velocity, laterally migrating fluid



For the case of stagnant fluid, the one-dimensional pathway approach presented above is an appropriate model. For this case, the calculations already presented are representative. However, the lateral diversion model explicitly violates the one-dimensional assumption, and therefore a bounding approximation is required. In these analyses, it is assumed that the travel time from the surface to the elevation of perching is the same as was modeled previously, but the travel time from the perched water zone to the water table is minimal. This approach yields the shortest overall possible travel time, and therefore is useful for assessing the impact of this conceptual uncertainty. Note that this analysis assumes that lateral displacement of water and contaminants in perched zones is relatively small compared to lateral displacement in alluvial groundwater systems that are the source of deep percolation.

To perform these calculations, regions were identified within the canyons where intermediate groundwater has been observed, and it was assumed that the vadose zone pathway terminates at that location. This allows travel times to be bounded without explicitly modeling transport from the perching horizon to the regional aquifer. Figures 4-2b and 4-3b show the results of the travel time simulations for the alternate perched water conceptual model for each percolation scenario. Comparing these figures to their counterparts for the one-dimensional downward flow cases (Figures 4-2a and 4-3a), the differences in travel time are quite subtle. The regions with vadose zone travel times of less than 100 years remain approximately the same, and the travel times at the same location are only mildly impacted by the perched water conceptual model. For example, for the base-case infiltration scenario, travel times are shorter by about 15-20 years for the alternate perched water model, and for the high flux scenario, these differences are even smaller.

To understand this result, note that transport from the ground surface to the water table in the one-dimensional model is dominated by percolation through the matrix of the Bandelier Tuff. Therefore, terminating the transport pathway at the base of the tuff, as in the alternate perched water scenario, eliminates a relatively small portion of the total travel time to the regional aquifer. Of course, despite this insensitivity of travel time, the arrival location at the water table is potentially quite different for the two cases: this factor should be considered in specific cases of contaminant transport predictions.

4.1.3 Contaminant Transport Model Predictions—Representative Canyon and Mesa Sites

This section presents an overview of modeling studies focusing on two representative LANL sites. The first example models contaminant transport from a relatively dry mesa top, while the other addresses a canyon bottom.

4.1.3.1 MDA G Model

This section highlights the model developed for the Material Disposal Area G (MDA G) performance assessment. A detailed description of the model is provided in Appendix 4-B. A performance assessment (PA) is required to site and authorize permanent disposal facilities for radioactive waste. The purpose of the PA is to demonstrate that performance metrics related to protection of human health and the environment are not likely to be exceeded for a specified period of time. Performance objectives and periods of compliance vary according to the characteristics of the radioactive waste being disposed, but groundwater protection for U.S. sites is always explicitly required for at least 1000 years. This study was designed to predict the groundwater pathway dose in support of the PA of MDA G, an active, low-level, solid radioactive waste site located at LANL, as shown in Figure 4-4 (Fig. 1 of Birdsell et al. 2000).

The three-dimensional unsaturated-zone flow and transport model captures the complex hydrogeology and topography of the site and yields radionuclide flux estimates to the regional aquifer. Within the unsaturated-zone model, the source release of radionuclides is computed for 38 waste disposal pits and four shaft fields, as shown in Figure 4-5 (Figure 3 of Birdsell et al. 2000), each contributing to the total inventory. The continued migration of radionuclides through the aquifer is calculated by using a three-dimensional model designed to maintain the temporally and spatially varying distribution of radionuclide flux from the unsaturated zone.

Due to uncertainty of model parameters, the results of these transport simulations contain intrinsic uncertainty. The greatest uncertainties associated with predicting aquifer-related doses from the site, according to Birdsell et al. (2000), are related to understanding of the mechanisms that control flow and transport within the unsaturated zone and the ability to model these mechanisms. To accommodate both parameter and conceptual model uncertainties, large parameter ranges are used to ensure that the range of calculations captures the behavior of the actual system. However, predicted doses using parameters from the most conservative ends of the uncertain ranges are still well below those that would cause concern.

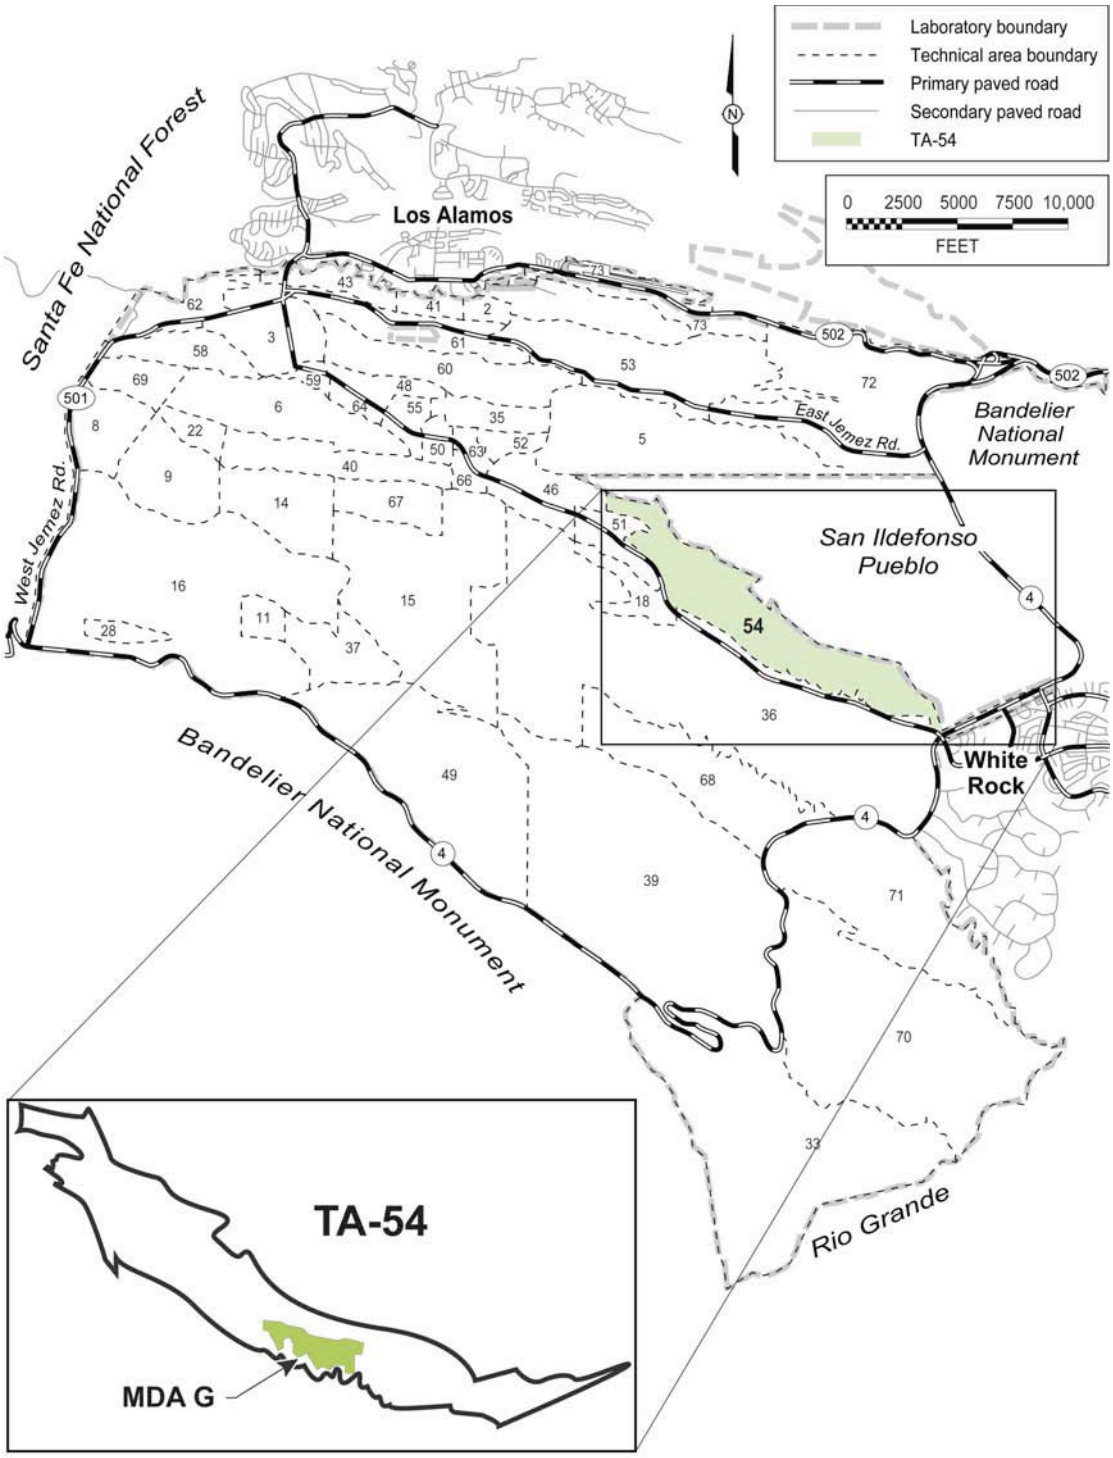

Figure 4-4. Study area for the performance assessment of MDA G, an active low-level, solid radioactive waste site located at LANL (from Birdsell et al. 2000).

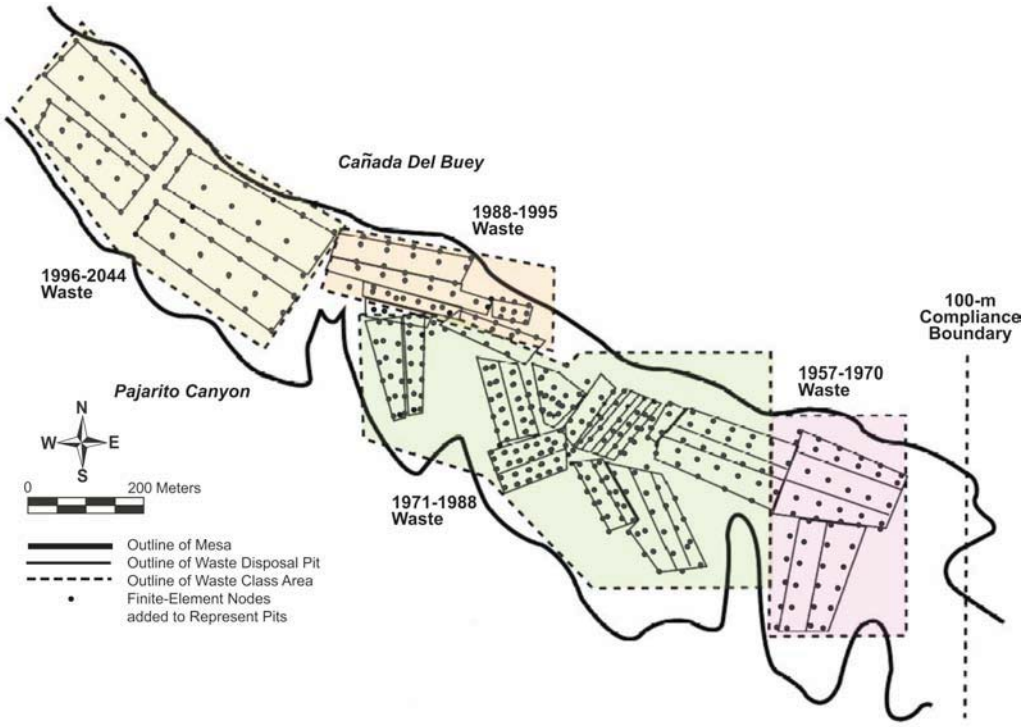

Figure 4-5. Approximate locations of the four waste classes and the 100-m compliance boundary used for the MDA G performance assessment. Also shown are the pit boundaries, internal pit nodes, and the outline of the mesa edge for the three-dimensional unsaturated-zone grid (Figure 3 of Birdsell et al. 2000).

The results recorded by Birdsell et al. (2000) indicate that the mesa-top infiltration rate has the greatest impact on the simulated migration of waste through the unsaturated zone. For the current conceptual and numerical models, it controls both the source release rate and subsequent downward solute migration. This uncertainty was bounded by considering a base-case flow field and high- and low-flow cases. A variation in mesa-top infiltration rate from 1 to 10 mm/yr (Appendix 4-B and Table 4-2) results in a range of six orders of magnitude in the 1000-year groundwater-related doses. Clearly, a good understanding of this key parameter is important to the dose assessment. However, because doses are so much less than the performance objectives, conservative yet realistic infiltration rates seem adequate for the MDA G site.

Table 4-2.
Infiltration Rates (mm/year) Used as Upper Boundary Conditions for MDA G Performance Assessment Simulations (fom Birdsell et al. 2000)

	Mesa Top	Cañada del Buey	Pajarito Canyon
1_1_20 (lowest flow case)	1	1	20
5_1_20	5	1	20
5_1_50 (base case)	5	1	50
10_1_20	5	1	20
10_5_100 (highest flow case)	10	5	100

Another source of uncertainty is related to flow in the deeper unsaturated-zone units for which few hydrologic data are available. The simulations take virtually no credit for transport times through the Cerros del Rio basalts, which make up more than 50% of the unsaturated zone. The transport results are based on the steady-flow assumption and on the use of matrix hydrologic properties for all tuff units at the site. Understanding of the response of this fractured system to transient flow events remains uncertain. Transient calculations (Birdsell et al. 1999) indicate that the steady-flow assumption is adequate because fluctuations in both saturation and contaminant flux rates dampen with depth, even when including fractures in the upper two units. Fracture infiltration studies (Soll and Birdsell 1998) lead to the conclusion that fracture flow is difficult to initiate and is short-lived in the upper two tuff units at the observed low field saturations. In addition, only Unit 2 and the uppermost portion of Unit 1v-u of the Tshirege Member, Bandelier Tuff, show evidence of significant fracturing (Krier et al. 1997), and these are excavated during disposal operations to depths where the tuff is poorly fractured. Therefore, the waste should not migrate through any highly fractured units until reaching the basalts. These observations help justify the use of the matrix hydrologic properties for the calculations.

In summary, travel times to the regional aquifer from locations on mesas are expected to be large (e.g., > 1000 yr) due to low infiltration rates and matrix-dominated flow. Calculations in this performance assessment model were deliberately conservative and therefore predicted travel times that were an order of magnitude shorter than the base case model presented in Section 4.1.2.1. Exceptions to this general conclusion are in the western portion of the Laboratory (see Section 4.1.1.1) and in locations where the natural mesa-top conditions have been disturbed by Laboratory activities.

4.1.3.2 Los Alamos Canyon Model

This section highlights the model developed for Los Alamos Canyon RCRA Facility Assessment investigations. A detailed description of the model is provided in Appendix 4-C. Los Alamos Canyon, as shown in Figure 4-6, is one of the most complex sites at the Laboratory. A number of technical areas have been or are currently located in or adjacent to the canyon, resulting in multiple release locations along the canyon. This study examined, through a synthesis of available data and the development of numerical models, fluid flow and contaminant transport in the vadose zone beneath Los Alamos Canyon. Modeling of the subsurface hydrology and transport in the vadose zone is also a challenging activity, given the wide range of infiltration rates, the presence of perched water, and the introduction of a host of contaminants of different chemical properties. Because the canyon serves as a collector of a wide range of contaminants, it was necessary to develop a model at the scale of the canyon, rather than at a smaller scale. The specific goals of the model are to

- Synthesize the available data and conceptual understanding of the vadose zone hydrology beneath Los Alamos Canyon;
- Produce a "base-case" numerical model of the subsurface vadose zone hydrology that ultimately can be used to predict contaminant migration rates and concentrations in fluids reaching the regional aquifer beneath the canyon;

- Quantify the uncertainties associated with those predictions by establishing the bounds on system behavior through a suite of possible models, all of which are consistent with the available data, but which bracket the range of possible behavior;
- Provide a simulation tool for predicting the fate and transport of contaminants in Los Alamos Canyon under different assumed hydrologic and ER stewardship scenarios; and
- Demonstrate a model development methodology that can be used in studies of other canyons on the Pajarito Plateau.

This work focuses on the hydrology beneath Los Alamos Canyon, as a first step toward developing a predictive tool that can be used to simulate contaminant migration in the canyon. Since water is the carrier fluid for the contaminants of interest, constructing a realistic flow model that captures the most important hydrologic processes of the vadose zone is an essential first step in the development of a reliable model. Although the study primarily restricts attention to flow issues, tritium transport in the vadose zone is also modeled. Tritium, in the form of tritiated water, is an excellent tracer for groundwater, and hence is included in this modeling study as a constraint on the flow model.

Figures 4-7 and 4-8 show a full three-dimensional view of fluid saturation and a series of two-dimensional vertical slices through the three-dimensional model. As expected, the figure shows wet conditions in the canyon, dry conditions in surrounding mesas. As with the two-dimensional model, this model result shows the overriding importance of the stratigraphy in controlling the water contents in the rock. The local infiltration rate also exerts a strong control on the results. Directly beneath the canyon, fluid saturation is much higher within a given stratigraphic unit than in other parts of the model domain, a reflection of the high infiltration in the canyon.

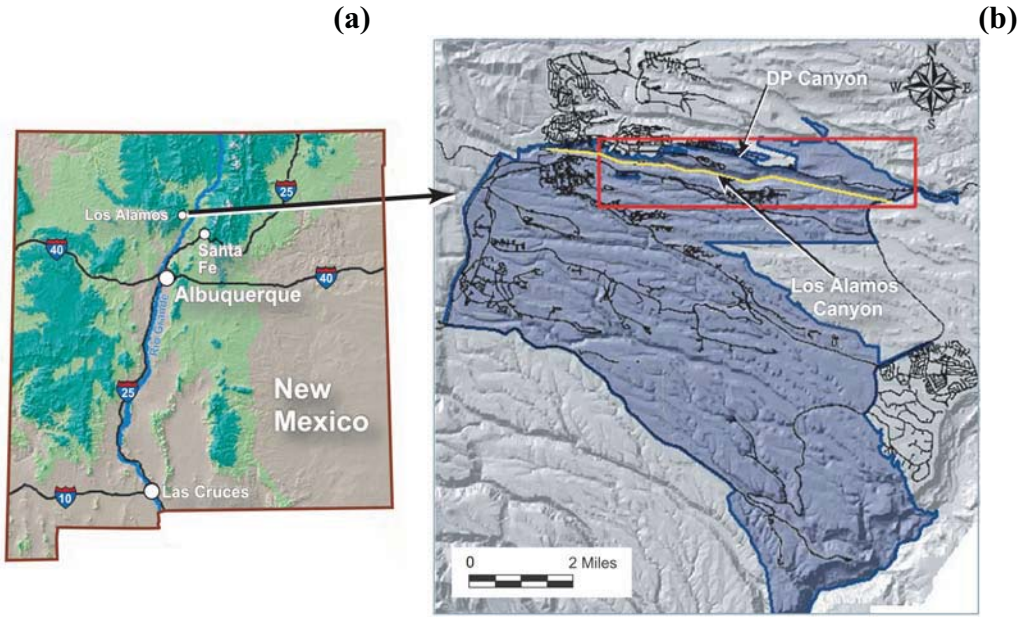

Figure 4-6. Location of Los Alamos, New Mexico (a), Los Alamos Canyon study area, and the flow and transport model domain (b). The shaded blue area is the LANL property; the red box indicates the areal extent of the three-dimensional model domain; and the yellow line is the trace of the two-dimensional model domain.

Volumetric water content is the primary measurement used to evaluate the model results because adequate data on water content are available from virtually all vadose zone characterization wells. The fits to the data are presented for three different levels of infiltration rates, i.e., the base-case infiltration map, a map with infiltration scaled down by a factor of three from the base map, and a map with infiltration scaled up by a factor of three (Figures 4-C-7 and 4-C-8). It is evident from the following comparisons that the model is able to capture the general features of data:

- The base infiltration map does an adequate job of jointly matching the water content profiles in these wells, despite the different stratigraphy and position relative to the canyon bottom.
- Good fit for LADP-4 illustrates the adequacy of the model in capturing the fluid saturations in the Tshirege Member (not present in the two-dimensional model), as well as in a region where infiltration rates are taken to be significantly lower than in Los Alamos Canyon at LADP-3.
- The need to apply significantly lower infiltration near LADP-4 is best understood by comparing the water content model and data for these two wells. The significantly wetter conditions in LADP-3 are simulated in the three-dimensional model through the setting of high infiltration in the canyon.

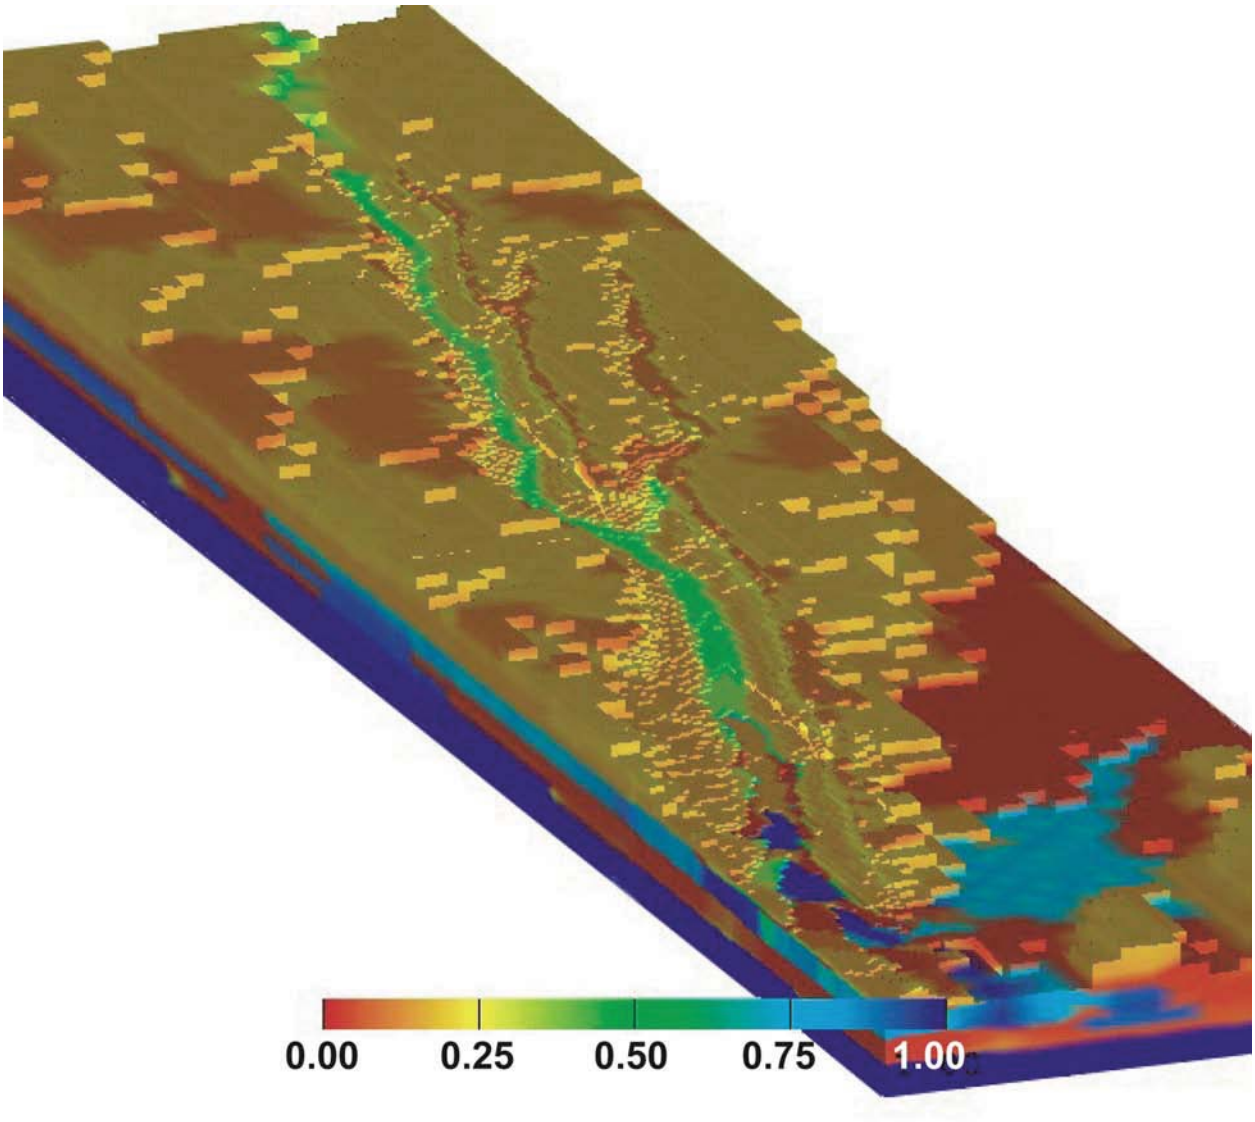

Figure 4-7. Three-dimensional flow model results, showing fluid saturation predictions (%) through the model domain (full model view).

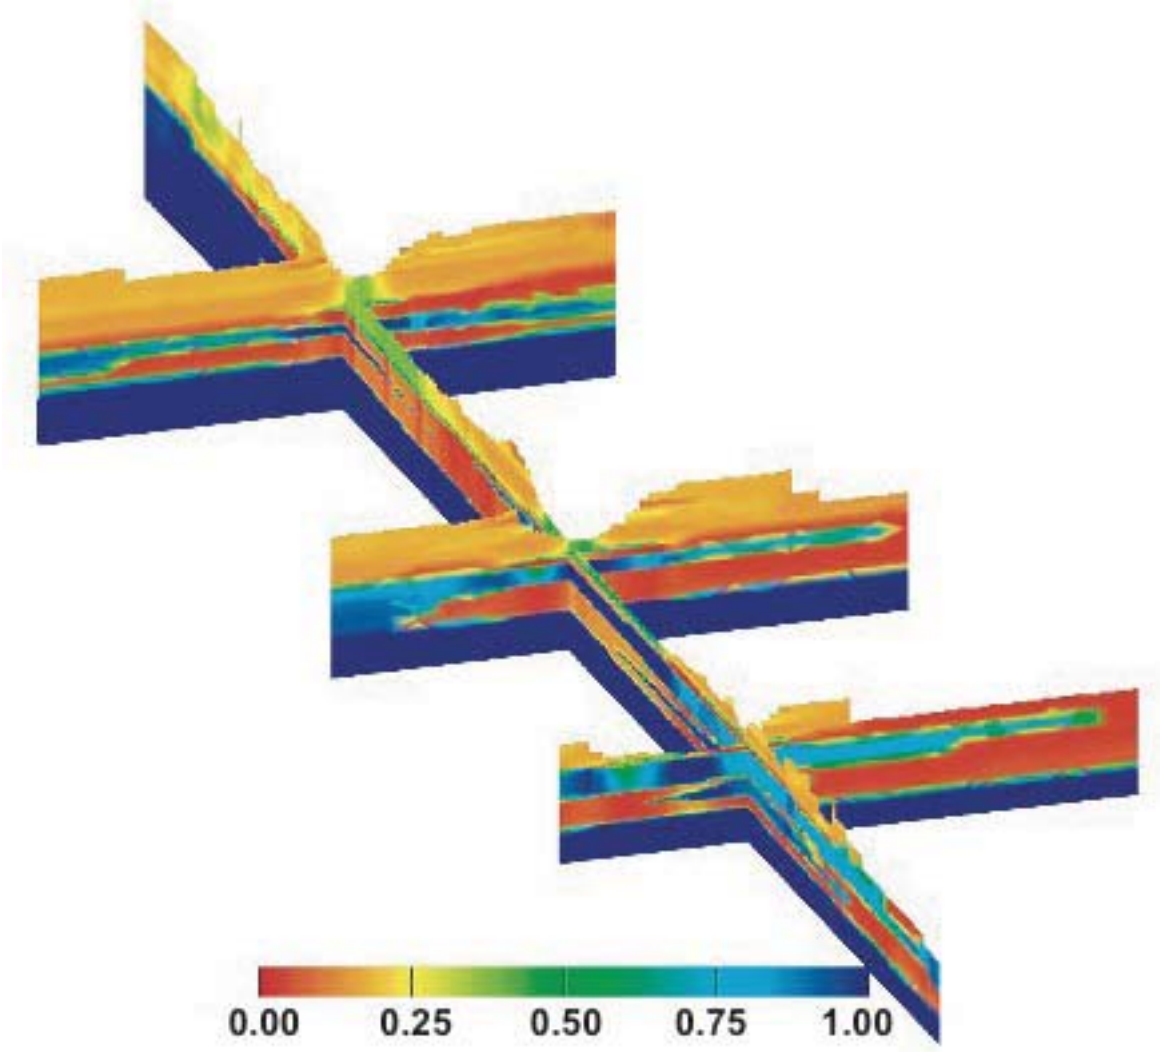

Figure 4-8. Fence diagram showing fluid saturation predictions (%) along one north-south and three east-west cross-sections.

Tritium transport model results are presented to further demonstrate the validity of the model and to explore important processes occurring in the vadose zone. Figure 4-9 is the three-dimensional model prediction of the tritium concentration of fluid reaching the water table in the year 1999. The model results are consistent with the available field data, indicating that regional aquifer fluid collected in well R-7 has undetectable levels of tritium, whereas TW-3 and R-9 show that tritium has reached the regional aquifer. Determining the ability of the model to reproduce the field data more quantitatively is difficult because of mixing of the tritium percolating from the vadose zone with regional aquifer fluid and the subsequent mixing of contaminated and clean fluid in the wellbore itself. The latter difficulty is especially acute for the water supply wells, which may draw water from hundreds of feet of screened length.

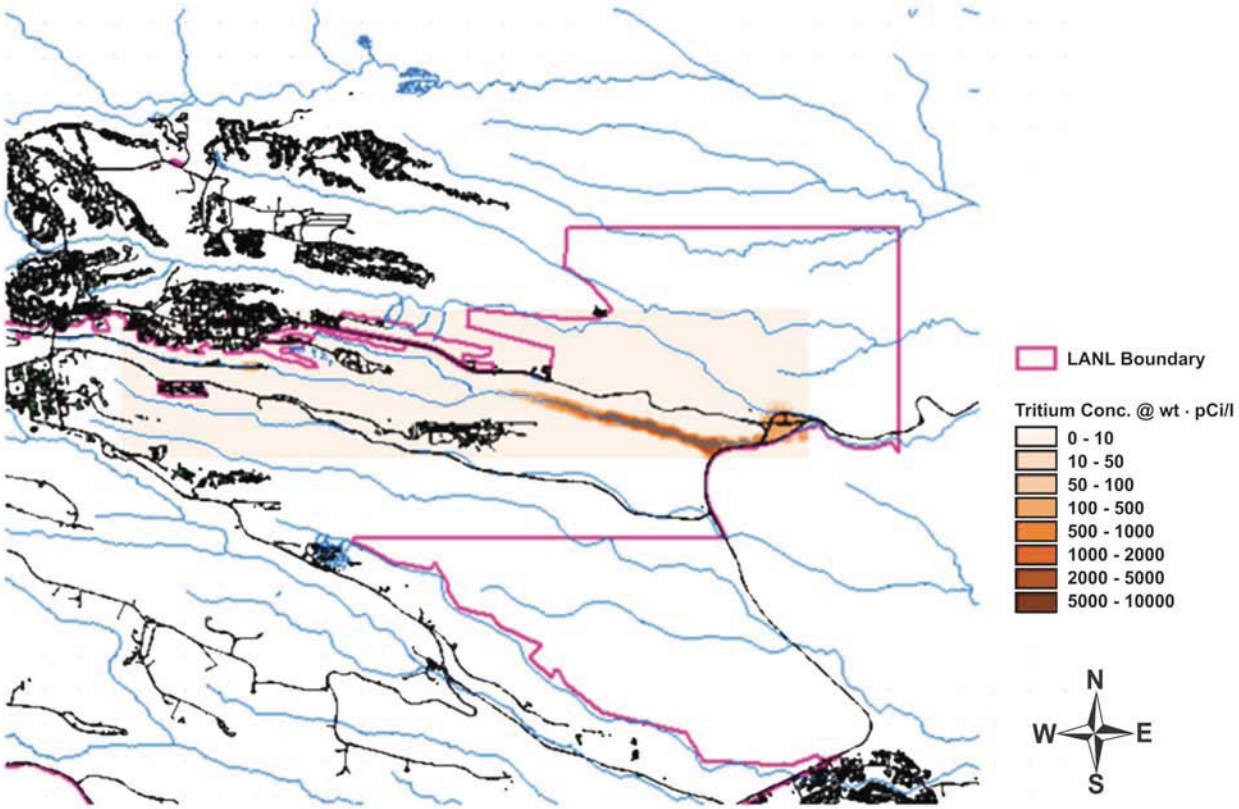

Figure 4-9. Three-dimensional model predictions of the tritium concentration of fluid reaching the water table in the year 1999. Significant, above background concentrations are predicted along the canyon at locations downstream of where the Bandelier Tuff is not present in the canyon bottom.

As a final comparison to the available data, we contrast the model results with regional aquifer water supply well O-1. However, because contaminant transport sources from Pueblo Canyon (north of Los Alamos Canyon) were not included in this model, the conclusions related to O-1 are more qualitative. For this comparison, monitoring information published in LANL (2001) is used. Contaminants tritium, perchlorate, and nitrate are all thought to be nonsorbing in this system, and thus the combined results of all three contaminants are used in this interpretation. Well O-1 has been found to contain measurable levels of perchlorate at about a 5 ppb level, nitrate levels higher than at other regional aquifer wells in the area, and consistent, above-background levels of tritium in the 30-40 pCi/L range. All observations point to both Laboratory-derived contaminants and effluent discharges from Los Alamos County. Past releases in Los Alamos and Pueblo Canyons have traversed the entire vadose zone. The present model explains these observations as a consequence of the hydrostratigraphy along the canyon, with rapid travel times at locations where the Bandelier Tuff is thin or non-existent.

Contrast these results with the transport model for MDA G presented in Section 4.1.3.1. Most important, travel times through the vadose zone are predicted to be orders of magnitude larger

for this mesa site than for transport from the bottom of a wet canyon. These travel-time results are consistent with the site-wide vadose zone results presented in Section 4.1.2. Infiltration rates, which directly impact transport velocities, are much larger in a canyon setting, in which all water in a catchment is channeled to the canyon bottom. A significant percentage of that water will escape evapotranspiration and percolate into the deep subsurface along the canyon. In contrast, a mesa top typically provides opportunity for water to run off as surface water or to be lost as evapotranspiration. Moreover, mesa sites have thick sequences of tuff with exceptionally low matrix flow rates. Therefore, percolation rates are much lower.

4.2 Numerical Models of Flow and Transport in the Regional Aquifer

The first numerical model for the regional aquifer was developed in 1998 in support of the LANL Groundwater Protection Program (LANL 1998). A number of related models have been developed since then, in support of both the Groundwater Protection Program and the Environmental Restoration Program, at a variety of spatial and temporal scales according to the requirements of the particular model application. In general, there have been three goals for these modeling studies:

- Integrate and interpret 3-D site-wide hydrologic and hydrostratigraphic data, to provide a quantitative basis for developing and testing site-wide conceptual models.
- Predict fate and transport of contaminants in the regional aquifer, in order to optimally place monitoring wells and inform risk assessment studies.
- Provide guidance in prioritization of data collection activities, highlighting the importance of those data that could most reduce numerical and conceptual model uncertainty.

As the Hydrogeologic Workplan has progressed, the data sets supporting the modeling studies have been steadily expanding. Updating the model with larger data sets has identified weaknesses in the modeling approaches and prompted changes in the methodology. This iterative process of data collection and model update and evaluation has significantly increased our understanding of the regional aquifer.

4.2.1 Previous Numerical Models

Two models have previously been developed by the USGS for the regional aquifer of the Española Basin, the aquifer system which provides drinking water to Los Alamos, Santa Fe, and Rio Arriba counties, as well as numerous pueblos. In contrast to the LANL modeling effort, these models were developed primarily to address water supply issues—particularly impacts of pumping on streamflow. The first was developed by Hearne (1985), using a computer code he wrote himself. The second was developed by McAda and Wasiolek (1988) (and later refined by Frenzel (1995), using the MODFLOW code (McDonald and Harbaugh 1988). At present, various local and state agencies continue to refine and apply both of these models to water supply issues in this basin.

In many ways, these two models are based on a similar conceptual model of the basin aquifer. Key elements of this conceptual model are as follows: (1) most inflow to the basin occurs as recharge in the mountains flanking the basin and along stream channels within the basin, and

(2) most discharge occurs to the Rio Grande and the lower reaches of its tributaries. A smaller portion of the total inflow and outflow occurs through lateral boundaries (i.e. up to 20% discharges to the Albuquerque Basin), due to structural and topographic features that limit inter-basin flow. The conceptual models of aquifer properties assume that hydraulic conductivity is strongly anisotropic, due to laterally discontinuous bedding features in the Santa Fe Group. The aquifer behaves as confined or leaky-confined, although no large-scale confining beds or low-permeability zones have been identified.

The lateral boundaries of the two models, shown in Figure 4-10, roughly coincide with the extent of basin-fill rocks in the southern portion of the basin (south of Española). Both models use specified flux boundaries to represent losing stream channels. Recharge is applied as specified flux, either at lateral boundaries (representing mountain block recharge) or along the upper model surface (representing recharge along stream channels or areal recharge). Discharge is to the Rio Grande and lower elevations of its major tributaries (specified head and head-dependent boundaries) and to the Albuquerque Basin (specified head in the case of the McAda model).

The conceptual model shared by these models is one of a complex transition from unconfined to leaky-confined conditions at depth, caused by relatively fine-scale bedding features in the rocks that provide resistance to vertical flow. Exact numerical implementation of this complexity is virtually impossible. The Hearne and Frenzel models treat the upper surface of the aquifer as a water table condition. Aquifer properties change from unconfined (top layer) to confined (lower layers); no discrete confining layer is present. Resistance to vertical flow is represented by anisotropy factors ($Kx/Kz \sim 100 – 1000$).

One significant difference between the models is the representation of large-scale heterogeneity. The Hearne model (which only includes the Santa Fe Group aquifer) treats the aquifer as homogeneous and anisotropic, with the numerical grid aligned in parallel with the dip of the beds in the Santa Fe Group. This approach allows the model to reproduce vertical upward head gradients measured in several wells in the eastern basin. The McAda and Frenzel models apply a somewhat ad hoc zonation of aquifer properties, based loosely on pump test results and the need to achieve an adequate model calibration to the data.

Appendix 4-D, Section 3, presents a comparison of inflows and outflows (steady-state, predevelopment) between the two models, as well as more recent estimates of inter-basin flow derived from USGS studies in the Albuquerque Basin.

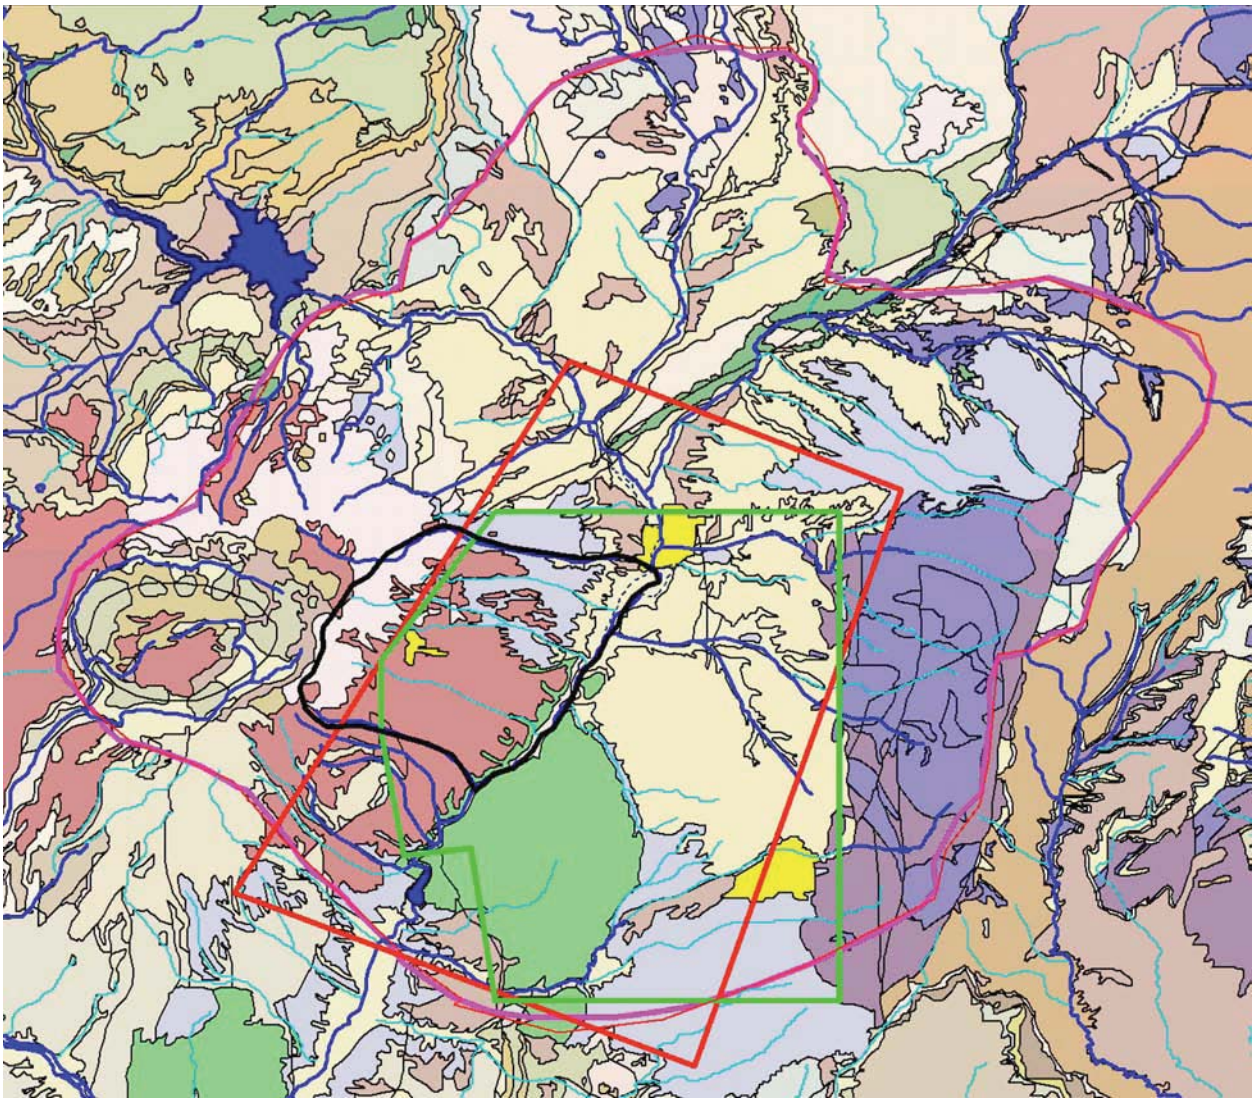

Figure 4-10. Geologic map of the Española Basin. Model outlines: green – McAda-Wasiolek model; red – Hearne model; pink – LANL basin-scale; black – LANL site-scale.

4.2.2 Overview of LANL Model Development

Unfortunately, both the USGS models of this aquifer system place a model boundary along the western edge of LANL; therefore, use of these models for the LANL site would be compromised by boundary effects (Anderson and Woessner 1992). To ensure that all model boundaries were far from the area of interest (LANL) and to incorporate the possible influences of regional flow on local conditions, a new flow model for the basin was developed. This model not only extends the western boundary farther than the existing models, to minimize boundary effects on site-scale simulations, but it also includes the major recharge areas for the basin. The inclusion of the recharge areas for the basin allows for a more comprehensive approach to estimating fluxes of water through the aquifer, as will be discussed below. The basin-scale model has been used to estimate aquifer properties, to estimate fluxes through the aquifer, to examine the possible influences of pumping in the Buckman wellfield on groundwater beneath the plateau

(and vice versa), to understand regional trends in groundwater quality, and to provide boundary conditions to small, site-scale models.

This initial basin-scale model has undergone several revisions, including increasing grid resolution in the vicinity of LANL and improving the hydrostratigraphic framework model that governs the spatial distribution of aquifer properties. In 2000, a site-scale model for the Pajarito Plateau (see Figure 4-10) was developed with much higher grid resolution than could be achieved with the basin-scale model, and was coupled to the basin-scale model (Keating et al. 2003). The site-scale model has been used to provide contaminant transport calculations, to conduct capture zone analyses, to support monitoring well siting decisions, and to estimate groundwater velocities.

Both the basin and site-scale models have been developed to address site-scale (several to tens of kilometers) issues and this has driven model development. For example, the methods of estimating aquifer properties (Section 2.8) emphasize large-scale effective properties of rocks. These properties may be different than what might be measured at very small scales, such as injection/recovery tests over small intervals in characterization wells or borehole geophysics-based estimates. These models (and model parameters) would not be appropriate for simulating the details of fine-scale (sub-kilometer) flow and transport.

Smaller-scale models have been developed. For example, a 2-D radial model was developed to evaluate the utility of using an R-well as an observation well during a pump test at O-1. In addition, a suite of 2-D and 3-D "box" models were developed to test conceptual models of flow and transport through the highly heterogeneous strata of the Puye Formation.

A principle of model development is to begin simply and gradually add complexity as needed. Even though the models, in their current form, are quite complex, they are much simpler than the aquifer itself. A major focus of the approach has been to implement numerical strategies that are flexible, so that the impacts of conceptual model uncertainty and parameter uncertainty on model predictions can be quickly assessed within a single modeling framework, without building entirely new models.

It should be emphasized that these models are for the regional aquifer only, and therefore do not include alluvial or perched groundwaters. The current versions of the models do not explicitly include springs, so pathways and travel times to springs have not been simulated.

4.2.3 Numerical Framework

All of the LANL models have employed the FEHM code (finite element heat and mass transfer) (Zyvoloski et al. 1997), publicly available software. Underlying this code is a sophisticated grid generating software, LaGrit (Trease et al. 1996) which can capture the details of complex hydrostratigraphy known to exist at this site. For conditions of saturated flow and transport (i.e. the regional aquifer), FEHM solves the same set of equations as do other more widely used codes, such as MODFLOW. The choice of this software for the LANL models was driven by the need to couple saturated zone simulations with vadose zone simulations (which use FEHM), to represent complex hydrostratigraphy, and to eventually investigate complex geochemistry and thermal effects (ongoing work). FEHM is well suited to these types of problems, since

temperature and density dependent fluid properties can be accurately accounted for. Some of the more simple simulations presented here do not utilize the specialized capabilities of FEHM and LaGrit; these simulations could easily be repeated using a code such as MODFLOW and one would expect the results to be identical (assuming grid resolution and boundary conditions were identical).

Figure 4-10 illustrates the lateral boundaries of the LANL models. In the basin model, boundaries were located such that they were far from the LANL site and coincided with either hydrologic features or structural boundaries. The northern and southern boundaries coincide with major structural transitions between the Española Basin and basins to the south and to the north, where the thickness of the Santa Fe Group aquifer declines from several thousand feet (in the center of the basin) to near zero at the basin margins (Shomaker 1974) (Cordell 1979). The basin is separated from the Albuquerque and Santo Domingo basins to the south by a structural high, a prong of older sedimentary rocks, and several major fault zones. The site-scale model boundaries coincide with a surface water divide (to the west), and surface water courses to the north (Santa Clara Creek), to the east (the Rio Grande), and to the south (Rio Frijoles).

Figure 4-11 illustrates generalized flow directions within the basin and locations of inter-basin flow along model boundaries. Stream gage locations are also indicated; these data are described more in Appendix 4-E.

The LaGrit software (Trease et al. 1996) was used to develop numerical meshes for the basin and site-scale models. A grid refinement algorithm was used that allows extra detail to be placed where needed in the mesh, such as in the vicinity of LANL. The most refined grid, the site-scale model, has a horizontal resolution of 125m × 125m and a vertical resolution of 12.5m in the shallow layers of the aquifer beneath LANL.

4.2.4 Hydrostratigraphy

In contrast to previous models of the basin aquifer, the LANL models define aquifer heterogeneity on the basis of a separate 3-D hydrostratigraphic framework model. This model was developed with surface geologic maps, published cross-sections, geophysical studies, and numerous well logs (see Section 2 and Carey et al. 1999). It is based on structure and lithology, rather than hydrologic data. The degree of detail present in the model is much greater beneath the Pajarito Plateau than for other portions of the basin. This is primarily because there are many more deep characterization wells on the plateau than elsewhere in the basin, but also because of the more complex volcanic and sedimentary stratigraphy of the plateau compared with most other portions of the basin (e.g., Buckman wellfield, entirely within Santa Fe Group sediments).

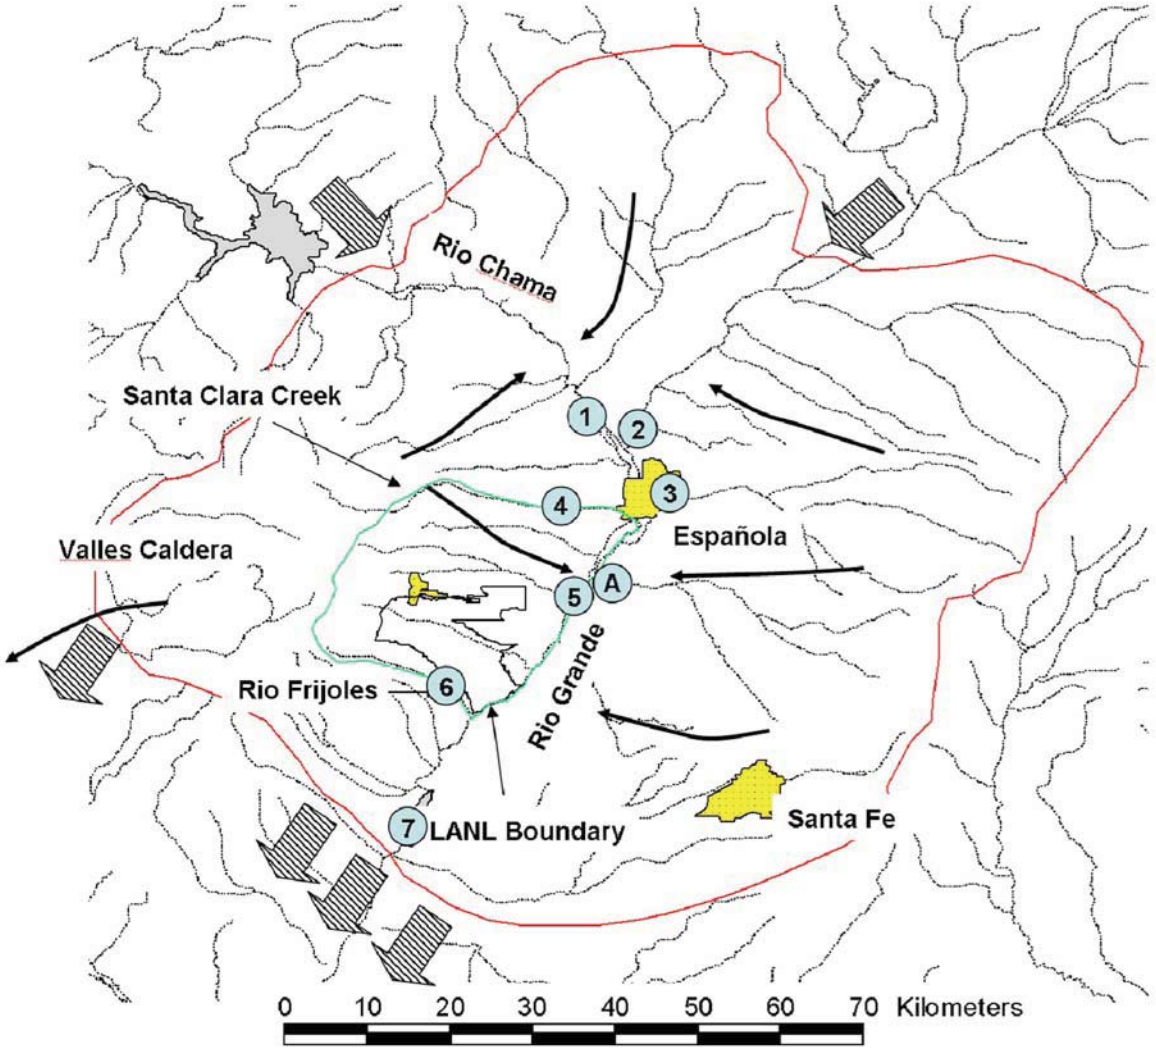

Figure 4-11. The Española Basin, with the basin-scale numerical model outline shown in red, and the site-scale model outline shown in green. Black arrows are generalized groundwater flow directions, based on regional water level data (Keating et al. 2003). Striped arrows indicate groundwater flow between this basin and adjacent basins. Circled numbers refer to USGS stream gages: (1) Rio Chama at Chamita; (2) Rio Grande at San Juan; (3) Santa Cruz River; (4) Santa Clara Creek; (5) Rio Grande at Otowi; (6) Rio Frijoles; (7) Rio Grande at Cochiti. The circled "A" indicates the mouth of Pojoaque Creek (see Appendix 4-E).

The process of overlaying the framework model on the numerical mesh for the flow and transport models has been described in Keating et al. (1999). This process assigns every node in the numerical mesh to one of the defined hydrostratigraphic units (see Appendix 4-D, Section 1). The high vertical resolution in the site-scale model is important to the representation of thin basalt flows and thin gravel beds within sedimentary units known to exist in this aquifer. The current model (September 2004) does not contain the latest update to the 3-D site-wide geologic model, which will include additional mapping from 2003 through 2005, drilling, and characterization data.

4.2.5 Boundary Conditions

The upper boundary of the model domain represents the top of the saturated zone; these nodes are either no-flow (no recharge), specified flux (recharge), or constant head (river nodes which may either recharge or discharge to the aquifer) (see Figure 4-12). Generally, the lower boundary of the model (no-flow) is the contact between the Precambrian basement and younger rocks. An exception to this is locations where the Precambrian basement crops out (such as in the Sangre de Cristos); in these areas we sub-divide the basement into a shallow, permeable block and a lower, impermeable block.

In the current model formulation, the entire thickness of the aquifer is assigned properties consistent with leaky-confined or confined conditions ($Ss = 10^{-3.3} – 10^{-4.5}$ m^{-1}). In the current numerical framework, unconfined conditions can be approximated by assigning the shallow layers a relatively high value of specific storage. However, changes in the thickness of the aquifer due to changes in the water table elevation are ignored. This approximation is reasonable for flow simulations in the vicinity of LANL, due to the large thickness of the aquifer (>3000 m) relative to measured changes in heads with time (30–50 m over 50 years). However, transport simulations may be sensitive to this approximation and the model is currently being modified accordingly.

4.2.6 Recharge

Recharge from the unsaturated zone is represented as a specified flux boundary condition along the top of the model. The spatial distribution of recharge across the plateau and in the larger basin is complex and inherently uncertain, since recharge rates cannot be measured directly. The model uses a simple approach to represent the spatial distribution of recharge. The advantage of this approach is that it can be easily manipulated to approximate a wide variety of recharge conditions; this flexibility allows for exploration of uncertainty in model predictions due to the inherent uncertainty of any recharge estimate. The disadvantage of this approach is that it does not capture very fine-scale detail. At present, the models have assumed that recharge is constant in time.

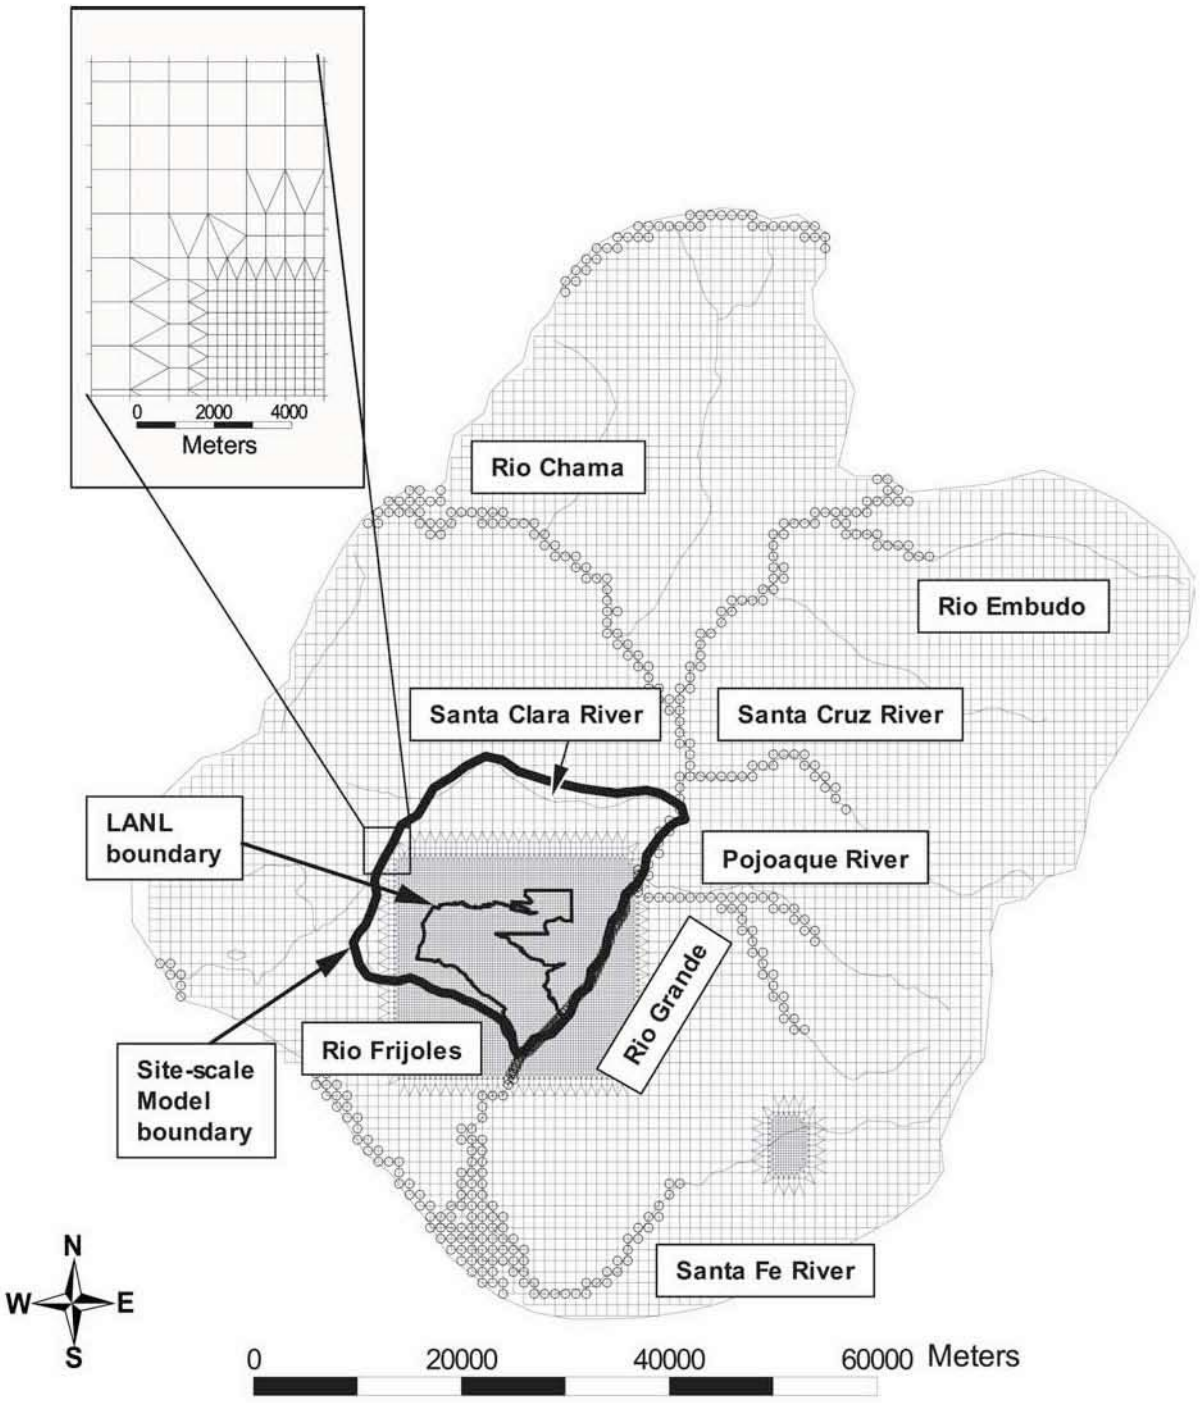

Figure 4-12. Basin model grid (plan view) with site-model boundaries indicated. The inset shows the northwest corner of the octree mesh refinement region. The circles show the locations of specified head nodes along rivers and basin margins.

There are three types of recharge accounted for in our model: areal recharge (which occurs mostly in the mountains), perennial stream channel recharge (for major streams in the basin), and ephemeral stream channel recharge (for many of the channels on the plateau). Areal recharge is determined as a function of precipitation (which is, in turn, determined by the surface elevation and long-term average precipitation trends in the basin). The details of the recharge model are presented in Appendix 4-D, Section 2. This numerical framework can be used to generate multiple possible models of recharge. Several examples are shown for the site-scale model in Figure 4-13; these different models all impart the same total flux to the aquifer. Table 4-3 shows the parameters used for these examples. For a more extensive discussion of regional and plateau recharge distributions, see Section 2.7.3.1.

4.2.7 Discharge at Rivers and Interbasin Flow

The Rio Grande, its lower tributaries, and locations where inter-basin flow occurs (upper Rio Chama, upper Rio Grande, lower Rio Grande, and Jemez River) are modeled as specified head nodes. Model-predicted fluxes at these boundaries are described in later sections. Heads at the surface are determined using digital elevation model (DEM) data for the basin. Heads at depth along the Española Basin/Albuquerque Basin are specified in accordance with estimates of the water table elevation at this boundary and are constant with depth to the Precambrian boundary. The assumption of "specified head" along the Rio Grande is an approximation suitable for flow and transport calculations far from the river. This simplification is inadequate for addressing the details of stream/aquifer interactions at the Rio Grande and is currently being addressed.

4.2.8 Lateral Boundaries of the Site-Scale Model

The locations of the lateral boundaries of the site-scale model were selected with the expectation that fluxes across the boundaries (which are uncertain) will be small relative to the total flux through this portion of the aquifer. The basin model is used to estimate these fluxes, with estimates of corresponding uncertainty (Keating et al. 2003). Fluxes across these lateral boundaries are explicitly mapped, node by node, onto site-scale model boundaries. That analysis showed that uncertainty in fluxes into the site-scale model (from the north) and out of the site-scale model (to the south) due to basin model parameter uncertainty was relatively small. In contrast, flux uncertainty across the western and eastern boundaries was relatively large. These results are described in more detail below.

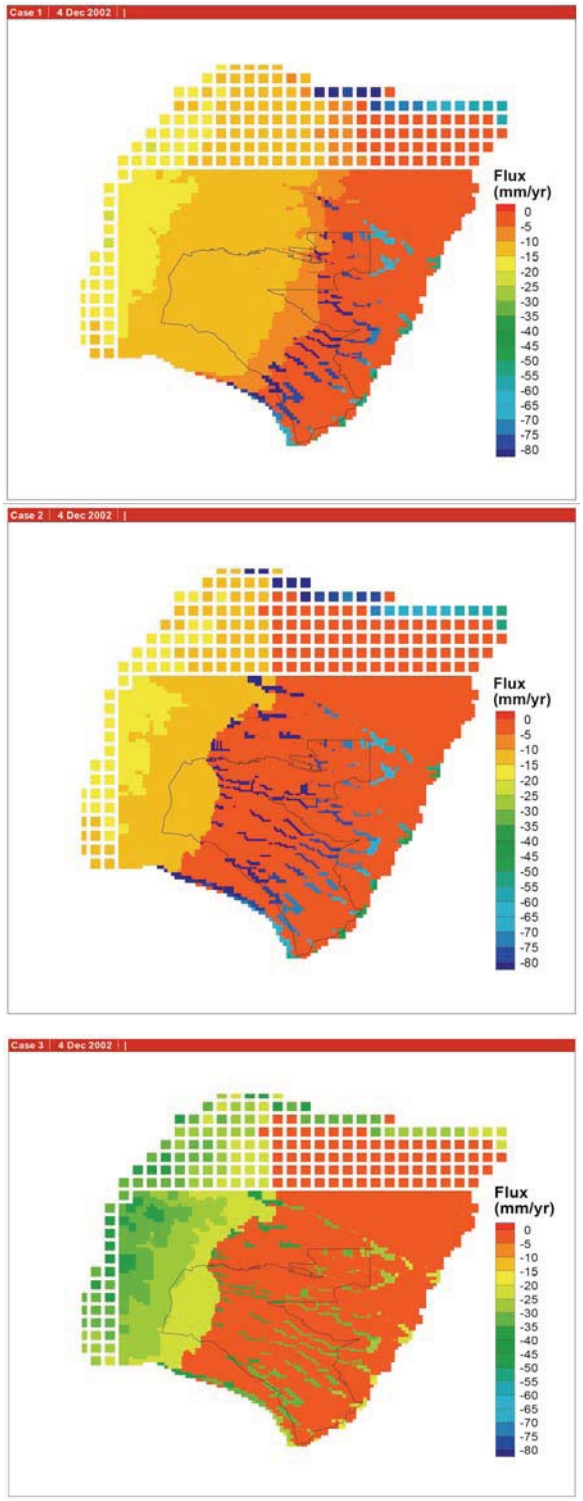

Figure 4-13. Examples of three recharge models, all imparting the same total flux. Model parameters are shown in Table 4-3.

Table 4-3.
Example Recharge Models, Shown in Figure 4-13.

	Case 1	Case 2	Case 3
Total recharge (kg/s)	200.3	200.3	200.3
Diffuse	122.3	70.6	145.2
Canyon-focused	78.0	129.7	55.1
Zmin (m)	2000	2200	2200

4.2.9 Data Used in Model Development and Testing

The datasets used in model development and testing are as follows: water level data, well construction and location data, water supply production data, hydrostratigraphy, stream channel location and elevations, hydrologic and structural boundaries for the basin, stream gage data, and selected geochemical data. The water level data, well construction and location data, water supply production data, precipitation data, stream gage data, and geochemical data are tabulated in Keating et al. (2005). Hydrologic divides (used to define model boundaries) and stream channel location and elevations were derived from USGS DEM data. Structural and geologic transitions used to define lateral basin boundaries were derived from Kelly (1978) and Shomaker (1974).

4.2.10 Flow Model Parameters

Model inputs are recharge rates, aquifer properties (permeability, specific storage), and stress (water supply production rates). Model outputs are heads and aquifer discharge (at constant head nodes along the Rio Grande, Rio Chama, and its tributaries, the Jemez River, and lateral boundaries). Other quantities such a travel times, flow directions, and well capture zones can also be derived from the model output.

As is the case in most groundwater systems, model outputs (heads and aquifer discharge) can be measured with much greater accuracy than model inputs (recharge rates and aquifer properties). This study employs the standard techniques of inverse analysis to derive model inputs (recharge rates and aquifer properties) from model outputs (heads and aquifer discharge). This is the same procedure widely used to derive aquifer properties from pump test data. The application of this method is somewhat unusual in that it acknowledges uncertainty in recharge, a complication that is usually neglected. This analysis provides information on aquifer properties and recharge, with quantified uncertainty, which can then be used to drive forward models and produce predictions.

The methodology used for inverse analysis is described in detail in Keating et al. (2000) and Keating et al. (2003). The three sets of calibration data are (1) pre-development heads (little or no impact from pumping), (2) transient heads (1946–2003), and (3) pre-development estimates of aquifer discharge to rivers. The data are listed in Keating et al. (2005). The details of the inverse analysis have changed over time, and the calibration data set has expanded as new wells have been drilled, computational resources have improved, and the hydrostratigraphic framework model has evolved. The aquifer properties derived from this process should represent larger spatial scales than those derived from short-term pump tests (days), since the transient data set

used represents a long period of time (55 years) and a widely spaced data set (several kilometers).

Table 4-4 illustrates several representative results for inverse analyses conducted using the basin- and site-scale models. See Keating et al. (2003; 2004) for details of these analyses. It is striking that the estimate for the lower Santa Fe Group is so much lower than pump tests conducted in the Los Alamos wellfield (completed entirely within the Santa Fe Group). This may be due to large-scale features, such as north-south trending faults, which would lower the effective permeability of the aquifer. Or this may be due to errors in the analysis or supporting datasets, such as a too low estimate of total recharge to the system. More detailed discussion of the hydrologic properties can be found in Section 2.8.

Figure 4-14 illustrates the degree of match between measured and simulated heads and fluxes at the basin scale, using the parameters shown in Table 4-4 (parameter set 1). Figure 4-15 shows the degree of match between measured and simulated hydrographs in the vicinity of LANL (parameter set 3). The magnitude of measured head response to 60 years of pumping (about 15 m in the central plateau, about 40 m to the east in the Los Alamos wellfield) is adequately reproduced, as is the recovery of heads in the Los Alamos wellfield after the cessation of pumping in 1975). Agreement between simulated and measured heads in water supply wells on a year-to-year basis is less accurate. Possible reasons for this, listed in detail in Keating et al. (2005) include both model errors and measurement errors. Improved fits would require explicit consideration of sub-annual variations in both water production and in measured water level responses.

4.2.11 Transport Model Methods and Parameters

The FEHM transport code employs one of two primary methods to simulate solute transport. The first is a particle-tracking methodology. This method can be used to simulate advection-only transport, which produces path lines and travel times that would be expected to represent the mean behavior of a conservative (non-reactive) solute plume. This method can also be used to simulate advective-dispersive transport, where thousands of particle paths are simulated and the number of particles present in any location represents solute concentrations. The second method is a direct solution of the advection-dispersion equation. This method can be used to simultaneously calculate the migration of multiple solutes, concentrations as a function of time and space, and a full suite of reactions with liquid, solid, and gas phases.

Table 4-4.

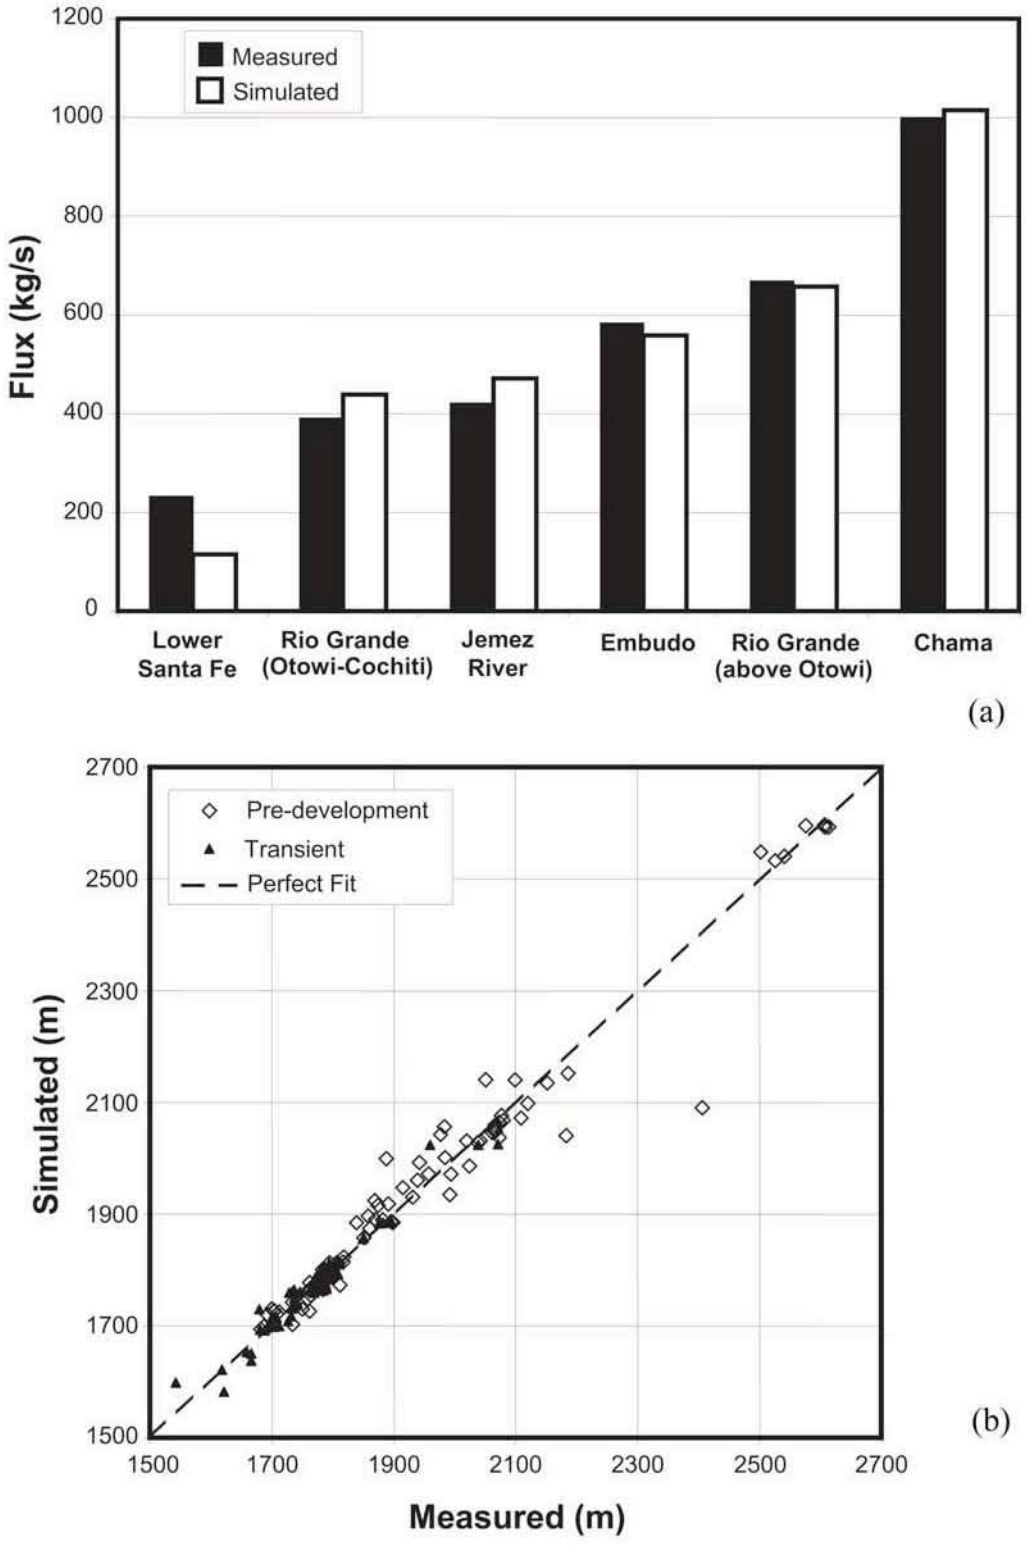

Figure 4-14. For the basin-scale model, comparison between measured and simulated (a) fluxes; (b) heads.

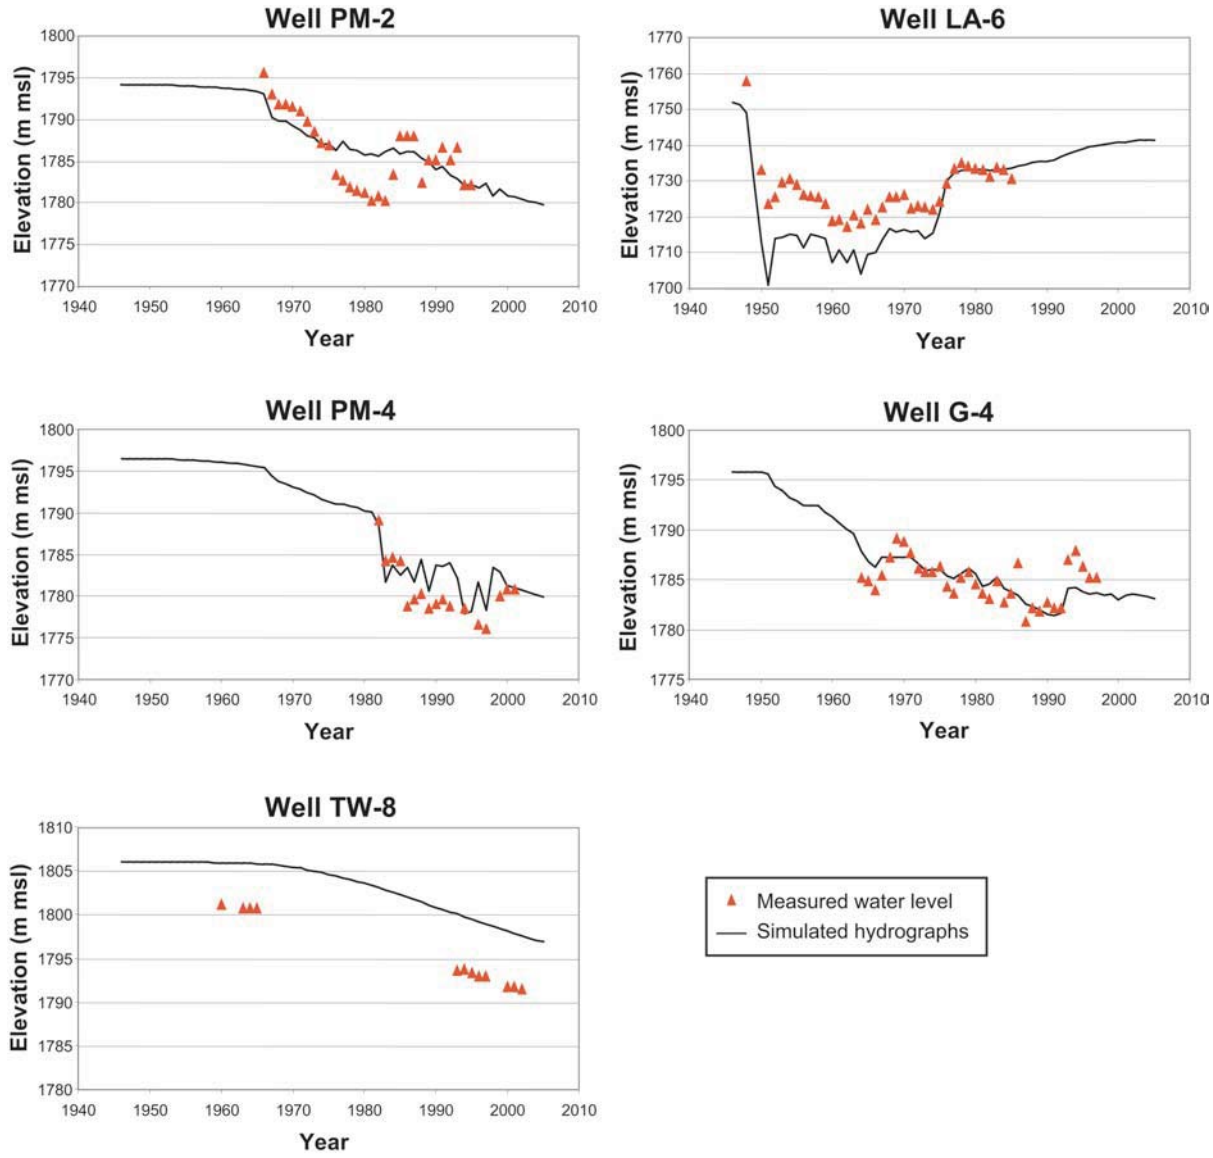

Figure 4-15. Comparison of simulated and measured hydrographs for representative wells on the plateau.

For nonreactive chemistry simulations, the particle-tracking methodology is preferable because it avoids the problem of numerical dispersion. Most of the analyses presented here use this method. One important limitation of this method is that the solution is invalid in portions of the numerical grid where elements are nonorthogonal (see Appendix 4-D, Section 1, Figure 4-D-2). However, in these calculations we restrict our analysis of particle-tracking paths to the fine-grid region at the site scale, thereby avoiding the problem.

Two critical parameters for nonreactive transport simulations are rock porosity (which is linearly proportional to travel time) and dispersivity (which controls the degree of spreading and mixing). Neither of these types of data has been collected in this aquifer at scales meaningful for site-scale transport simulations. Therefore, the model uses literature-derived values appropriate for the types of rocks present in this aquifer.

4.2.12 Model Applications

There have been three broad categories of model applications. The following subsections present brief examples of modeling studies for each category.

4.2.12.1 Category A: Integrate and interpret 3-D site-wide hydrologic and hydrostratigraphic data, to provide a more quantitative basis for testing site-wide conceptual models than was previously possible.

Many of the fundamental issues pertaining to the regional aquifer are questions that cannot be answered using data collection alone. Where are the predominant recharge areas? How much water is flowing through the aquifer? What are the large-scale hydraulic properties of the aquifer rocks? In what direction is water flowing? What is the pore water velocity of the groundwater? What effect has pumping had in the past and what effect will it have in the future? A great deal of characterization data has been collected over the past few years to address these questions, and the numerical models have been used as a framework for interpreting these data and providing at least partial answers to these questions.

1. Large scale fluxes. Keating et al. (2003) demonstrated the use of inverse and predictive analysis to examine the range of possible fluxes and recharge distributions that could explain the measured head data and stream gage data at the basin-scale. This approach acknowledges the uncertainty in aquifer properties and recharge rates, and attempts to determine to what extent quantitative estimates can be made. The aquifer property estimates that resulted from this approach, with uncertainty, are presented in Table 4-4 (parameter sets 1 and 2); the degree of agreement between measured and simulated heads and base flow gains are presented in Figure 4-14.

As shown in Figure 4-14, this analysis demonstrates that the basin-scale model provides a reasonable fit to measured head gradients and discharge to river reaches. The estimated elevation above which significant areal recharge occurs (2195 m, shown as a red line in Figure 4-16) matches almost exactly the location of the transition proposed by Wasiolek (1995). In addition, the estimated percent of precipitation that becomes recharge in the mountains (8%) falls within, although close to the low end of, the range of watershed study results (Appendix 4-E). The predicted outflow to the Albuquerque Basin of 5,801 acre feet per year (afy) is less than previous USGS studies of the Española Basin (McAda and Wasiolek 1988) and more recent studies of the Albuquerque Basin (14,300 afy) (Plummer et al. 2004). This value could be increased by increasing the percent of precipitation that becomes recharge and still be within the range of reasonable values. These results generally support the conceptual model of total basin-scale recharge and discharge fluxes (tabulated in Appendix 4-D and Appendix 4-E), as well as the generalized spatial distribution of fluxes simulated with the recharge model described in Appendix 4-D, Section 2. It also demonstrates the value, at least at large scales, of the 3-D hydrostratigraphic framework model.

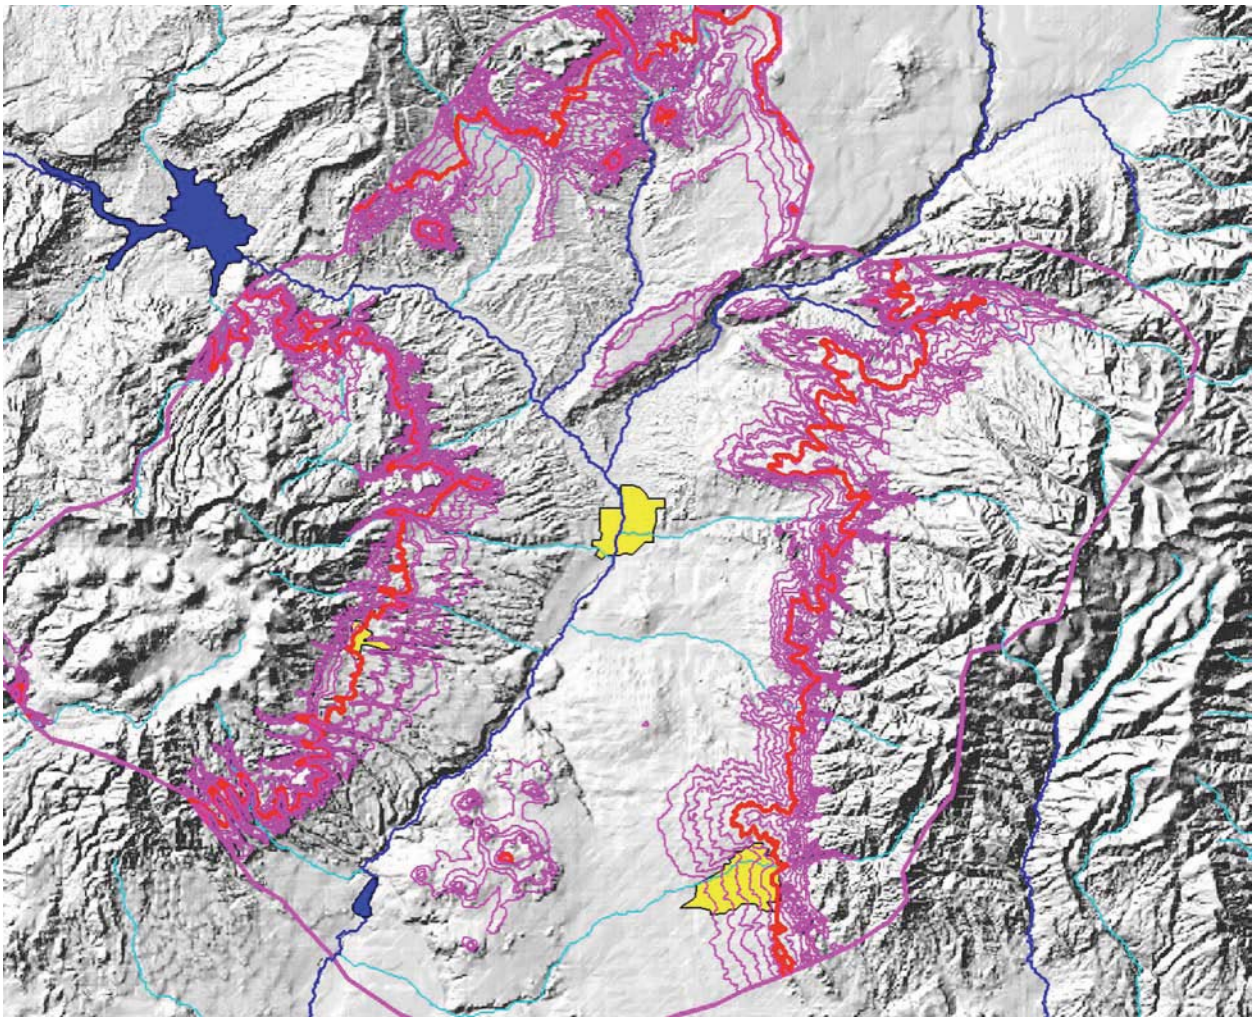

Figure 4-16. Location of predicted transition between significant areal recharge and negligible areal recharge (2195 m), and uncertainty bounds. Pink contours span the elevation uncertainty range.

The results of the basin-scale inverse analysis were used to estimate fluxes across the lateral boundaries of the site-scale model, with uncertainty. Figure 4-17 shows the results of this analysis. Fluxes perpendicular to flow (north and south) were calculated to be relatively small and showed much less uncertainty than fluxes parallel to flow (east and west). Significant flux is predicted to cross both the western and eastern boundaries; the high uncertainty of these estimates, however, means that this uncertainty should be explicitly considered when doing transport calculations that might be affected by these fluxes.

All these results depend on the streamflow analyses being reasonably accurate, the 3-D geologic model capturing the most important large-scale hydrologic features in the aquifer, and the method of inverse analysis fully exploring parameter uncertainty. This technique only explores the impact of numerical model parameter uncertainty; overall uncertainty in recharge and fluxes, which would include conceptual model errors, is undoubtedly larger.

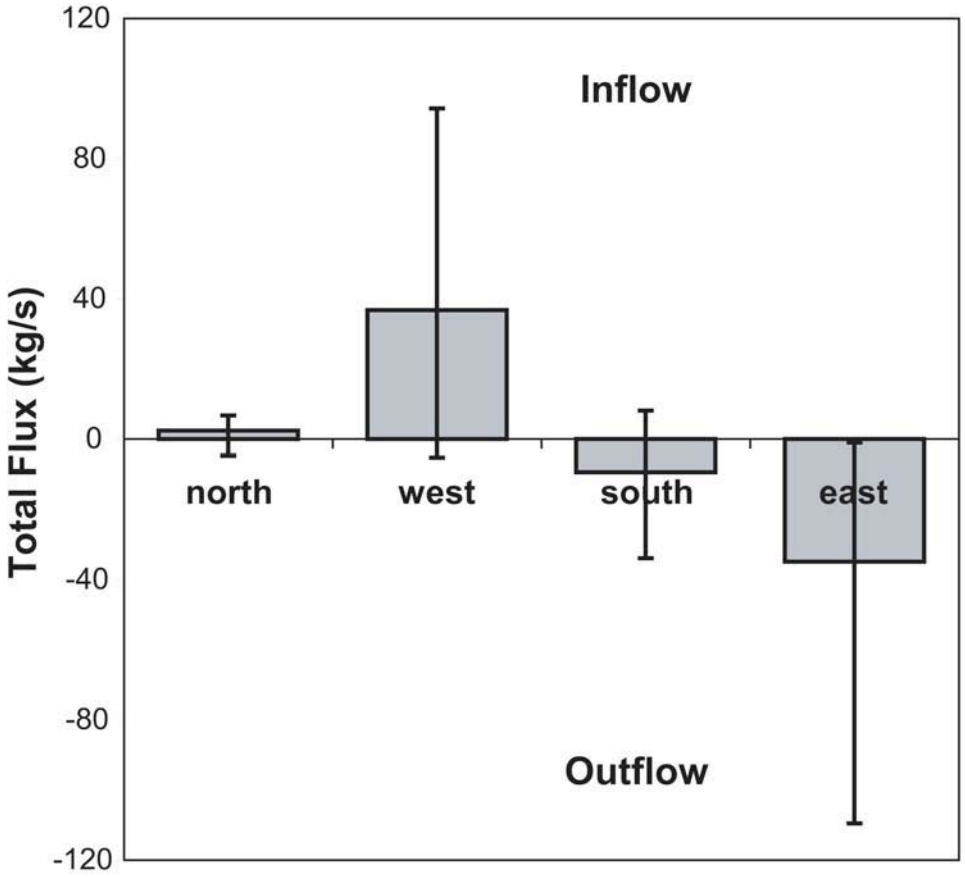

Figure 4-17. Fluxes across lateral site-model boundaries predicted by the calibrated basin model. Error bars represent the 95% nonlinear confidence intervals of estimates.

2. Small-scale fluxes, downgradient of LANL. A more recent study, Keating et al. (2004), used similar techniques to explore not only the question of uncertainty of total flux through the aquifer, but also uncertainty in fluxes through shallow portions of the aquifer immediately downgradient of LANL. This analysis is pertinent to estimates of contaminant transport away from the site. Figure 4-18 shows that parameter uncertainty in the site-scale model (including uncertainty in recharge rates and aquifer properties) contributes significantly to estimates of total recharge for the aquifer, but that the flux through the shallow portion of the aquifer immediately downgradient of the site is more certain. More detailed study of this result did highlight the large uncertainty in fluxes through a single basalt unit, however. Uncertainty in transport parameters, such as porosity, would produce a much larger impact on total velocity uncertainty; therefore, this study suggests that better measurement of fluxes and recharge would be of far less value than collecting site-specific estimates of porosity.

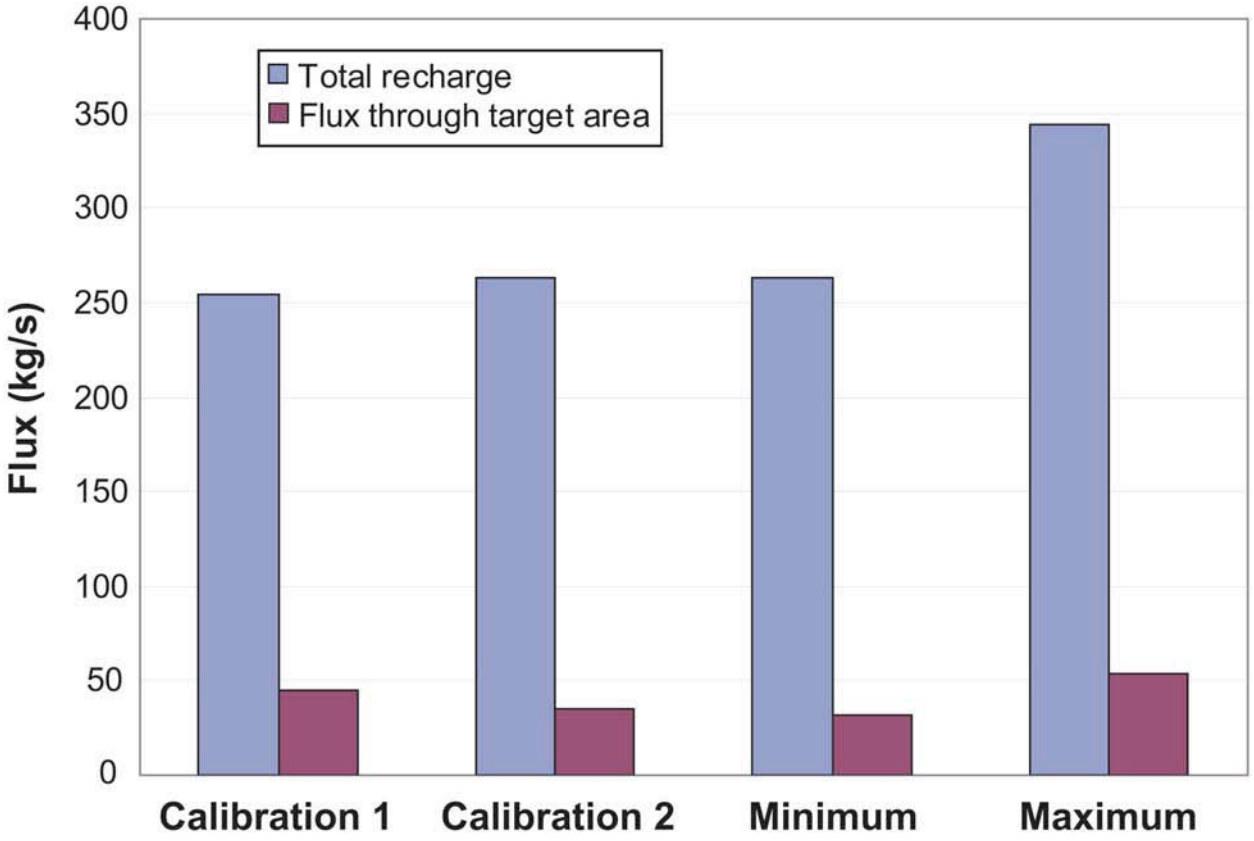

Figure 4-18. Results of predictive analysis, compared to two calibrated models. Blue bars indicate total recharge into the aquifer; red bars indicate flux through the shallow plane east of LANL.

3. Pore-water velocity. Pore-water velocities in the regional aquifer are very poorly constrained. Through modeling techniques described in this report, flow directions and fluxes can be surmised reasonably well, but velocities are very difficult to infer from hydrologic data alone. Contaminant distributions within the regional aquifer have been useful for identifying the location of fast pathways through the vadose zone, but since the exact location and timing of contaminant entry to the water table is highly uncertain, these observations do not constrain velocities in the regional aquifer. The best method for determining velocities is tracer tests.

The LANL model was used to produce a map of velocities at the water table (see Figure 4-19). These velocities are highly uncertain and are used only to illustrate a few key points. First, given the heterogeneous nature of the aquifer, groundwater velocity is likely to vary considerably over short distances. In this map, the fastest velocities are in the basalts where fracture flow (very low matrix porosity) is assumed. Second, flow on the eastern portion of LANL is predicted to be very slow. This is due to the very low permeability of the Santa Fe Group, which is prevalent at the water table east of LANL (see Table 4-4, Figure 2-10, and related discussion in Section 2.8.7).

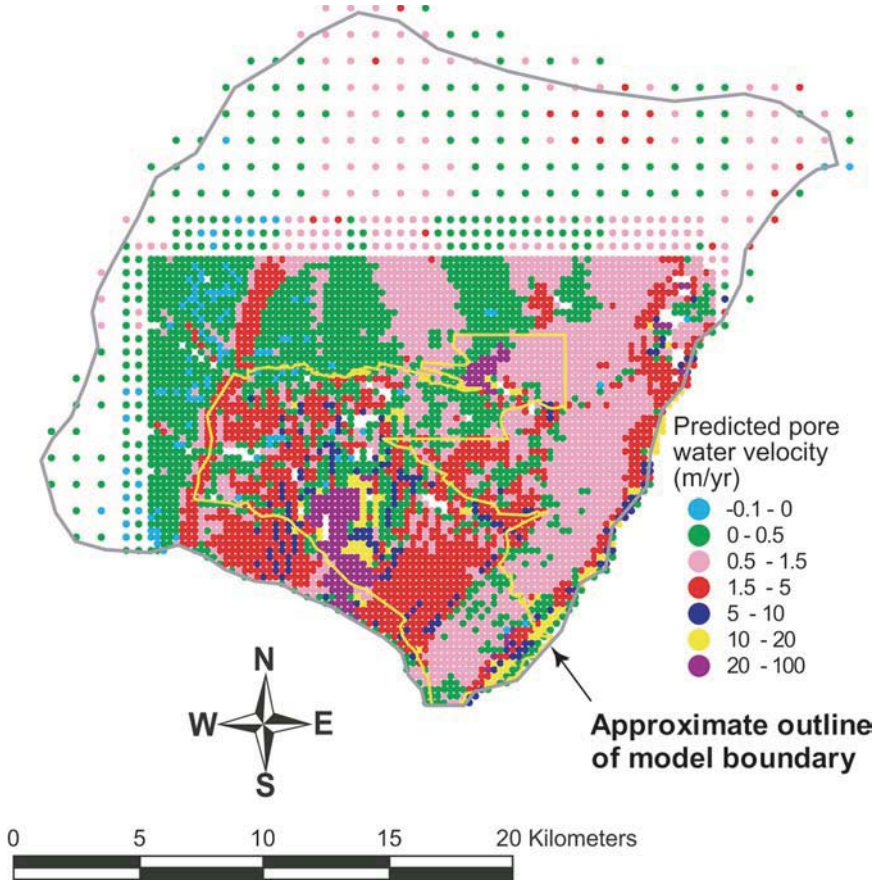

Figure 4-19. Model-predicted horizontal component of pore-water velocity at the water table, in m/yr.

The very slow velocities predicted by the model are consistent with ^{14}C data presented by Rogers et al. (1996a,b). These data are collected in both water supply wells (screened over the upper 2000 ft of the aquifer) and more shallow wells (DT5A, east side and west side artesian). Figure 4-20 shows a comparison of model predicted ^{14}C and measured ^{14}C presented by E. Kwicklis in Keating et al. (2000). One interesting aspect of this comparison is that the model underpredicts the age of the very old waters present near the Rio Grande.

In stark contrast to these predictions, Purtymun et al. (1984) produced a generalized map of pore-water velocity in the regional aquifer. His estimates assumed a uniform hydraulic gradient of 0.01 m/m, a uniform porosity of 0.1, and 1-D lateral flow. Using a 1-D version of Darcy's Law and hydraulic conductivity estimates from local pump tests, his resulting velocities ranged from 20 ft/yr (Los Alamos wellfield) to 345 ft/yr (DT wells). Assuming the high velocity estimate of 345 ft/yr, this would represent a travel time of 134 years across LANL from west to east (~9 miles). McQuillan (2003) used the chemistry data from White Rock Canyon Springs and TW-1 and an assumption of 1-D lateral flow to derive a velocity estimate of 358 ft/year (59 year travel time, ~4 miles). More recently, a report by Rice (2004), concurred with these earlier estimates.

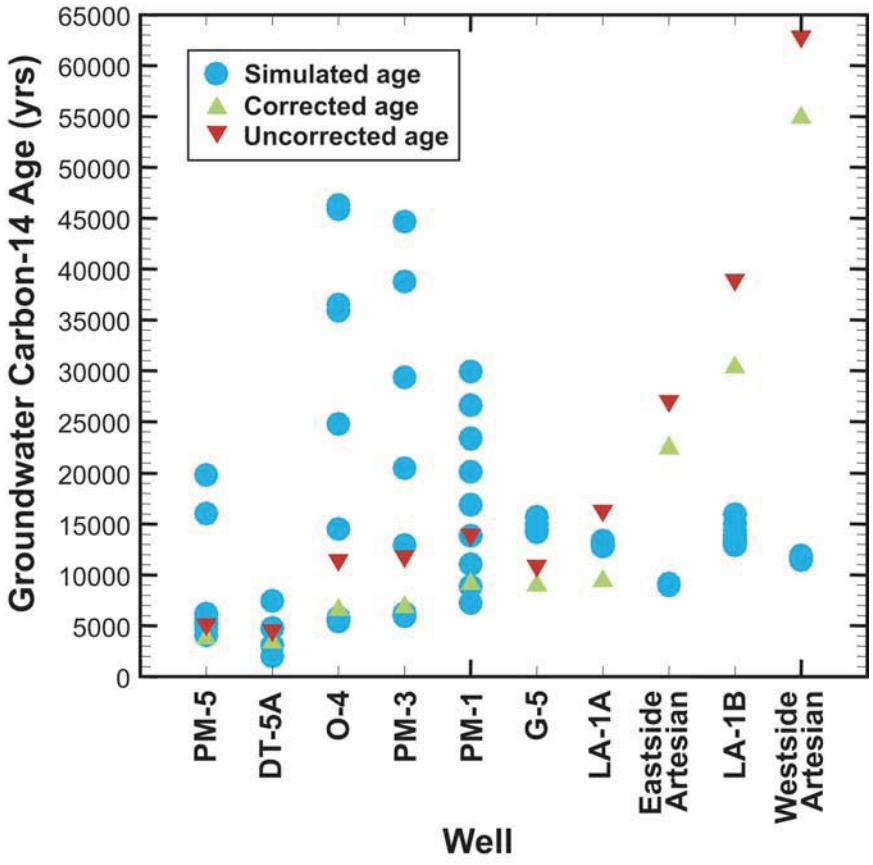

Figure 4-20. Comparison of simulated groundwater carbon-14 ages at nodes within the screened depths of wells with the corrected and uncorrected groundwater ages estimated from measured carbon-14 activities.

At present, it is impossible to compare the McQuillan and Rice calculations to the published LANL regional model predictions, because in the model (as configured for past applications) the springs are above the top of the model and therefore flow to the springs cannot be simulated. This is a subtle but very important distinction because the top of the model at present is entirely within the low-permeability Santa Fe Group in the vicinity of the Rio Grande, whereas slightly higher elevations (which include the springs) are within the more permeable units of the Puye Formation. Some springs also issue from the base of the Cerros del Rio lavas. If transport calculations to the springs are required in the future, minor adjustments to model boundaries will suffice to address this issue.

A more difficult question is that of measured hydraulic head gradients and lateral continuity of highly permeable rocks. The model honors measured gradients (in 3-D), the 3-D hydrostratigraphic framework model, and large-scale effective properties of rock units (see Table 4-4). At present, neither the measured 3-D hydraulic heads nor the permeability/hydrostratigraphy information supports the hypotheses presented by McQuillan and Rice. In such a complex aquifer, however, it is entirely possible that their hypotheses could be correct.

4. Effect of water supply well production

Capture zones. Understanding the influence of water supply production on the aquifer is important from the perspectives of both water supply and contaminant transport. From a water supply perspective, it is very important to know if the current rates of withdrawal are sustainable. From a contaminant transport perspective, an understanding of capture zones is critical to placement of a "sentry" well to protect a production well and to identification of which receptors are most at risk of contamination.

The LANL models have been used to evaluate the impact of water supply production in a number of studies. The philosophy of this approach has been to start simply and gradually add complexity only when needed. In a sense, all of these studies have illustrated the shortcomings of applying "simple" textbook methods of capture zone analysis to this site. Therefore, this is very much an ongoing study.

Using a relatively simple approach, Vesselinov et al. (2002a) calculated capture zones for the Buckman wellfield and all the Los Alamos wells. The motivation for this study was to determine if the LANL aquifer was within the capture zone for the Buckman wells, either at present or (possibly) in the future. This analysis was based on the standard "steady-state" assumption. The results, shown in Figure 4-21, demonstrated that a significant portion of the aquifer beneath LANL could eventually be captured by the Buckman wells. These results also showed the zones of influence of Los Alamos County water supply wells.

The assumptions inherent in this analysis are that current rates of production in water supply wells continue indefinitely until steady state is reached. Given the characteristics of this aquifer, this is not expected to occur for several hundred years from the present. Some wells in the Guaje field and some wells in the Pajarito field (PM-2, -4, and -5) appear to be stabilizing with respect to pumping; the assumption of steady-state may be applicable to these wells. However, given the dramatic fall of water levels in the Buckman wellfield over the past two decades, steady-state is far in the future. Given the uncertainties of water production over the next few decades (e.g. City of Santa Fe is expected to rest the Buckman field beginning in 2009, the steady-state approximation is questionable for this wellfield. It does, however, show one possibility that should be considered for planning purposes.

Vesselinov and Keating (2003) investigated the impact of dispersion and transients on capture zones analyses. Figure 4-22 shows the predicted capture zones when both dispersion (spreading of the plume) and transients (changes in source term and changes in water supply production) are included in the analysis. These authors concluded that significant errors were incurred when dispersion and/or transients were neglected in the analysis. The importance of transients (changing flow field in response to changing water production rates) highlights the importance of identifying when and where contaminants might reach the water table. For the same point of entry to the water table (for example, beneath Ten Site Canyon), a contaminant reaching the aquifer in 1960 might be captured by PM-1, whereas a contaminant reaching the aquifer in 1990 might be captured by PM-5.

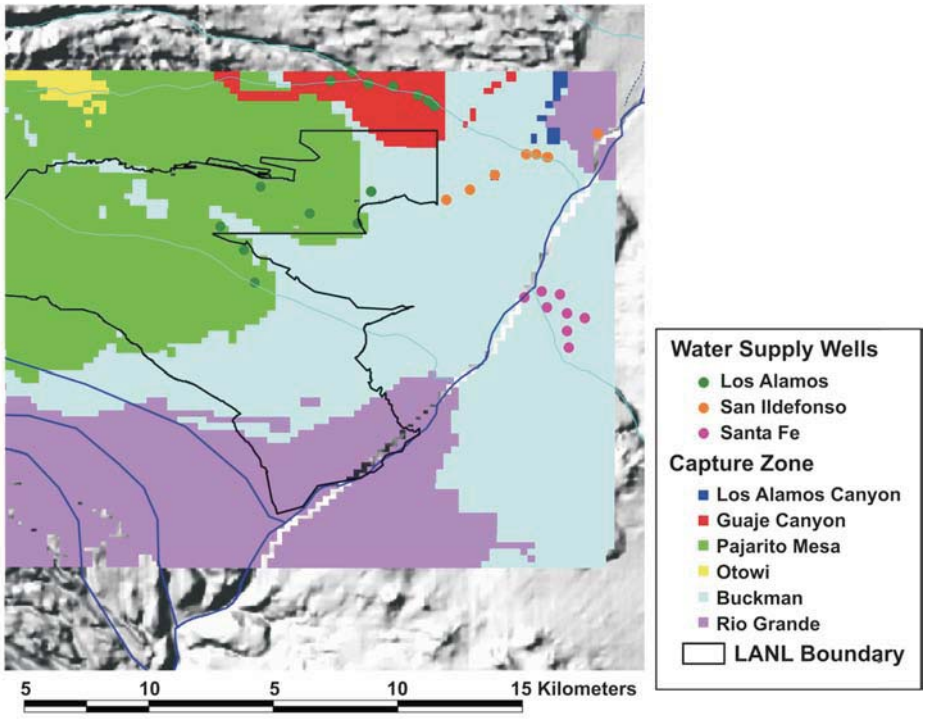

Figure 4-21. Predicted steady-state capture zones for wellfields in the vicinity of Los Alamos (from Vesselinov et al. 2002a).

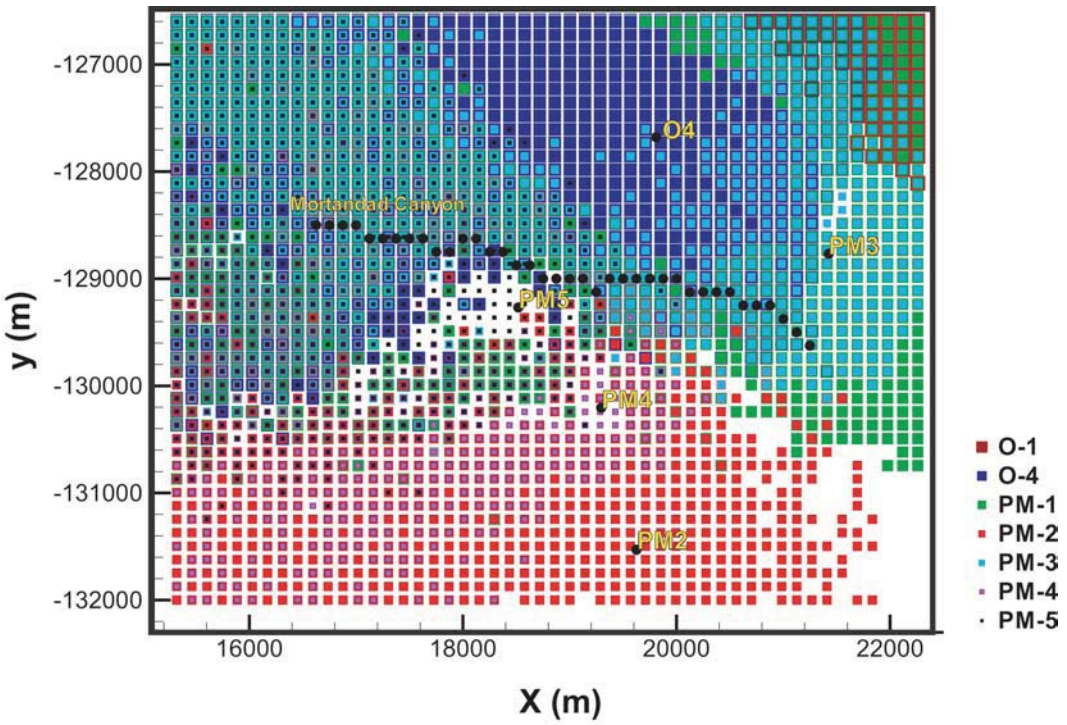

Figure 4-22. Predicted transient capture zones for wellfields in the vicinity of Los Alamos from Vesselinov and Keating (2003).

Effect on streamflow. In a basin such as the Española Basin, where surface water flow depends to a large degree on groundwater discharge, any water supply production will affect aquifer storage immediately and surface water flow eventually. When the aquifer reaches equilibrium with respect to pumping, the only continued impact will be on surface water flow. Wells drilled near the point of discharge will have a significant effect on surface water flow sooner than wells drilled far from the point of discharge.

Based on parameters shown in Table 4-4 (parameter set 3), the site-scale model was used to predict the percentage of produced water coming from storage and captured streamflow (or recharge) over the past 50 years. Figure 4-23 shows these results, demonstrating that the aquifer is still far from steady-state and that most produced water is still coming from storage.

5. Hydrostratigraphy. All of the studies listed above rely on the 3-D hydrostratigraphic framework model to define heterogeneity within the aquifer, according to the spatial distribution of approximately 15 units. Of course, with relatively sparse boreholes on the plateau there is uncertainty in the exact spatial extent of these units (Section 2.4.4). There also may be important heterogeneities within the hydrostratigraphic units as defined by the 3-D model.

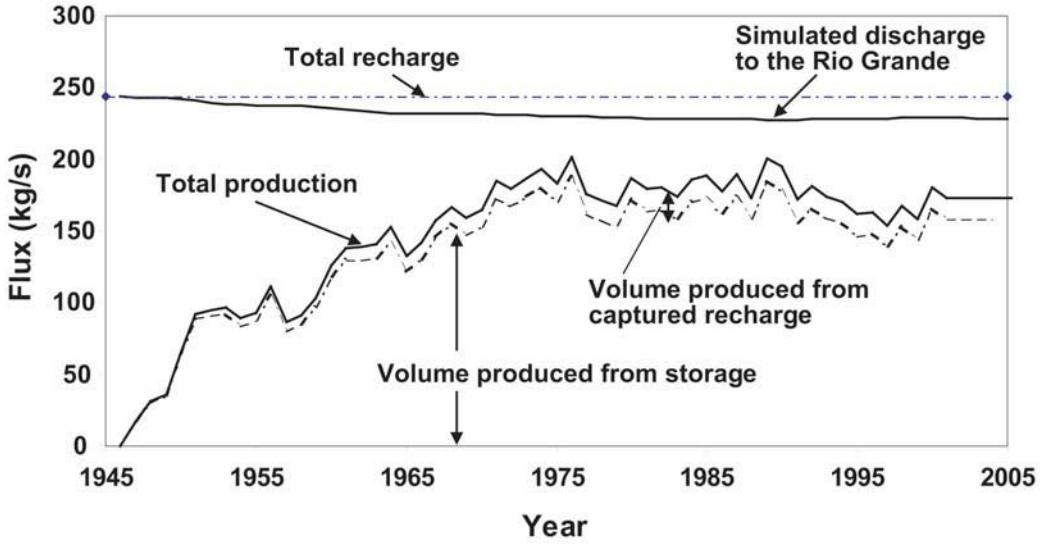

Figure 4-23. Simulated discharge to the Rio Grande, and estimated proportion of production in local wellfields that originates as storage and as captured recharge.

This study has devoted considerable effort to modeling heterogeneity within the Puye Formation at scales smaller than the 3-D hydrostratigraphic framework model. The Totavi Lentil is of particular interest, since it is characterized by beds of gravel which may be highly permeable. (Note: In situ hydraulic tests have been equivocal on this issue.) The current hydrostratigraphic framework model defines the Totavi Lentil as a continuous sheet of rock at the base of the Puye Fanglomerate; therefore model predictions that assign this unit a high permeability will be conservative (fastest travel times over long distances). Reneau and Dethier (1995) proposed a very different model of the Totavi Lentil, as a series of discontinuous north-south trending ribbons, separated from each other by terraces left behind as the Rio Grande downcut and moved westward over geologic time. Stochastic methods are appropriate for representing this type of heterogeneity, since the exact location of each of these narrow ribbons could never be known. Figure 4-24 illustrates one realization of a stochastic model of the Totavi Lentil, using Markov-chain transition probabilities based on data collected from geologic maps and measured outcrops (Carle 1996; Fogg 1989). This approach, and the data set that underlies it, are described in detail in Keating et al. (2000).

The Santa Fe Group (Tsf) has some intercalated Miocene basalts (Tb2; see cross-sections in Figures 2-12 to 2-19). To examine two extreme end-members, one might consider hypothetical cases where the deeper unit is either 100% Tsf or 100% Tb2. In 2002 a version of the framework model was created that explicitly identified zones that were uncertain, due to sparse borehole control. Figure 4-25 illustrates one such zone, which might be either a basalt or the Santa Fe Group. Figure 4-26 shows the resulting capture zone predictions, first assuming that zone is a basalt and then assuming that zone is the Santa Fe Group. By comparing the two figures, one can determine the impact of uncertainty of the hydrostratigraphy in this zone.

The Puye Fanglomerate also has beds of sand and gravel which, although of limited spatial extent, may be important in contaminant transport. Using textural descriptions from lithologic logs in R-wells, two different stochastic models of this type of heterogeneity were developed, as shown in Figures 4-27 and 4-28. Both of these methods show promise for use in future simulations.

The model calibration process itself can provide useful information about hydrostratigraphy. For example, if the conceptual model is that unit A is high permeability and unit B is low permeability, through the process of model calibration one can determine whether or not that conceptual model is consistent with large-scale head and flux data. This principle was used to test the conceptual model of a north-south trending high-permeability trough within the upper Santa Fe Group, proposed by Purtymun (1995). Carey et al. (1999) formulated this trough within the 3-D framework model as a fairly narrow feature (Figure 4-29a). Through the model calibration process, it was determined that this geometry was consistent with site-wide hydrologic data. Later, in a 2002 update of the 3-D framework model, this feature was significantly enlarged (Figure 4-29b). It was not possible to calibrate a model that assigned a high permeability to this large feature, so this model was discarded. These results suggest that the high permeability trough is likely to either be small, such as shown in Figure 4-29a, or exist as small, discontinuous patches.

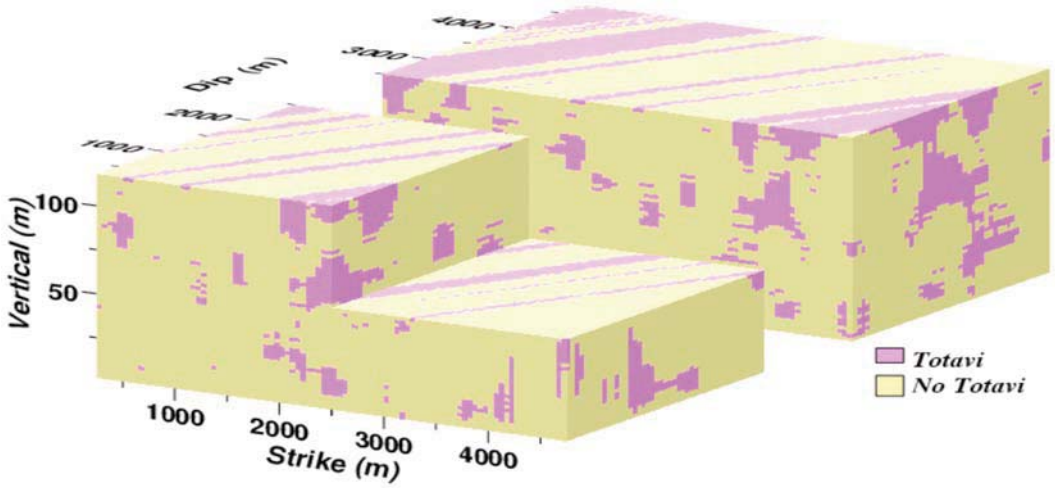

Figure 4-24. Heterogeneity within the Puye Formation; one realization of a stochastic Markov-chain model of the Totavi Lentil (dark pink). Model parameters are based on surface geologic maps and measured outcrops.

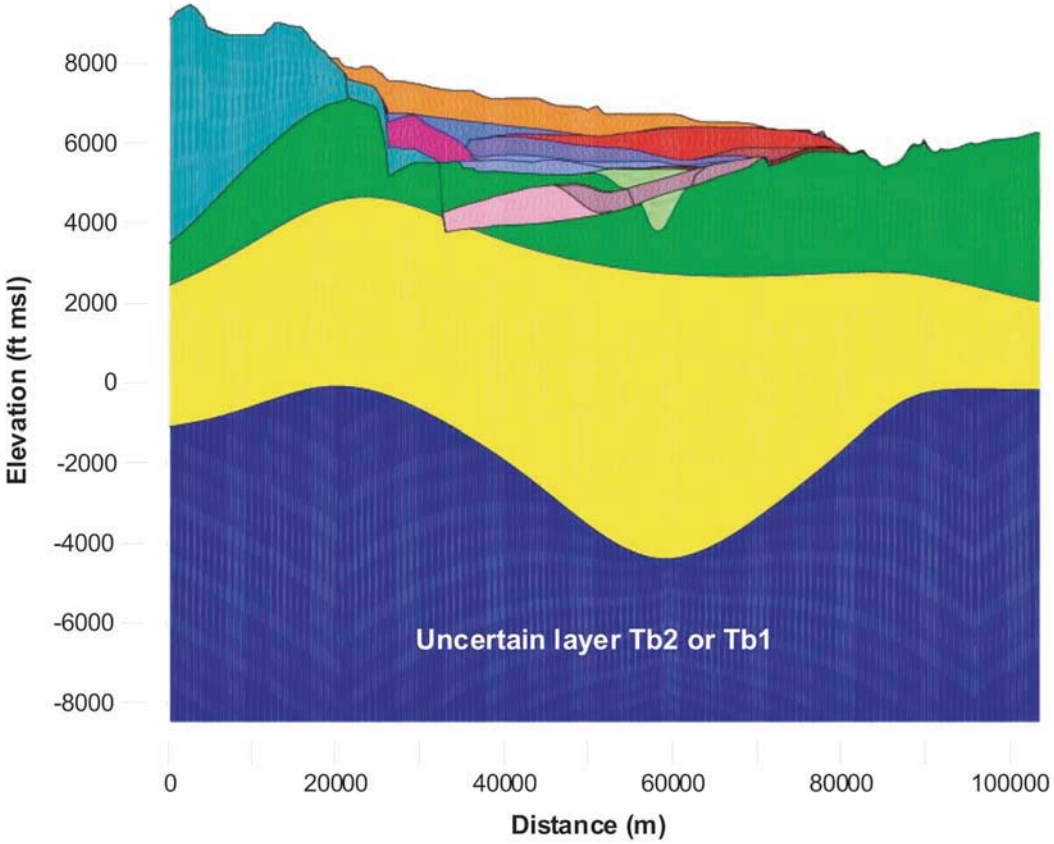

Figure 4-25. Cross section through hydrostratigraphic framework model, showing location of layer selected to perform a sensitivity analysis exploring the uncertainty in the geologic framework. The uncertain zone in pink was assumed to be either Tb2 or Santa Fe Group for the purpose of examining sensitivity.

4.2.12.2 Category B: Predict fate and transport of contaminants in the regional aquifer, in order to optimally place monitoring wells and inform risk assessment studies.

1. HE transport from TA-16. The first contaminant transport simulations were conducted in response to the discovery of high explosives (HEs) in the upper saturated zone at R-25. The first model predictions were based on a simple premise: that the aquifer is at steady-state (with current rates of production in water supply wells), and that the important heterogeneities were defined by the 3-D hydrogeologic framework model. HE was represented by non-reactive particles in the model, released at the water table both at TA-16 and beneath Cañon de Valle (assuming rapid downstream transport in the alluvium). Figure 4-30 illustrates these results, which show all the contamination eventually being captured by either PM-2 or PM-4. Travel is predominantly within the Puye Formation. Breakthrough curves, shown in Figure 4-31, suggested that travel times would be on the order of hundreds of years. These slow travel times are consistent with the observation that no HE has been found in monitoring wells drilled since this study, at distances relatively close to R-25. A later simulation using a transient flow field demonstrated that the steady-state analysis was sufficient for this problem.

This study was repeated in 2000 with a more realistic approach to modeling heterogeneity within the Puye Formation (see Figure 4-27). By using a stochastic approach, it was hoped to identify possible fast pathways that could significantly change our earlier result. Table 4-5 illustrates the results of this study, for ten different realizations of the Puye Formation. This result showed that given this model of heterogeneity, first arrivals of contaminants could appear at PM-4 in less than 100 years. The shorter travel times in this study are due to preferential transport through a heterogeneous medium.

None of these analyses considered the possible role of model parameter uncertainty on transport predictions. In particular, there was still concern about possible easterly-southeasterly pathways away from TA-16. Predictive analysis (Doherty et al. 1994) was used to explore the range of possible flow directions away from TA-16 that could be achieved by assigning a large number of combinations of permeability and recharge parameters, given the constraint that any model must still match measured heads and fluxes reasonably well. Figure 4-32 shows the results of this analysis, which found that only relatively small variations in flow directions were possible under variable model calibration criteria. The major caveat to this result is that it depends on the hydrostratigraphic framework model being accurate; the "true" uncertainty in flow directions is undoubtedly larger than that shown in Figure 4-32.

2. Siting a characterization well, R-13. One objective for R-13 was that it could eventually be used to monitor possible off-site migration within the regional aquifer of contaminants originating below Mortandad Canyon. Based on the similarity between ^{3}H data in alluvial and perched aquifer wells in Mortandad Canyon and in wells due east in Sandia Canyon (R-9, R-12, and O-1), a due easterly pathway had been proposed earlier. Numerical simulations, shown in Figure 4-33, suggested a slight southerly bend to flow directions due to pumping by PM-3, PM-4, and PM-5. This results in a steady-state flow field, which will tend to exaggerate the effects of pumping over what might be the effects of pumping at present. Based, in part, on these results, R-13 was sited along the LANL boundary, south of the due easterly flow path suggested by geochemical results.

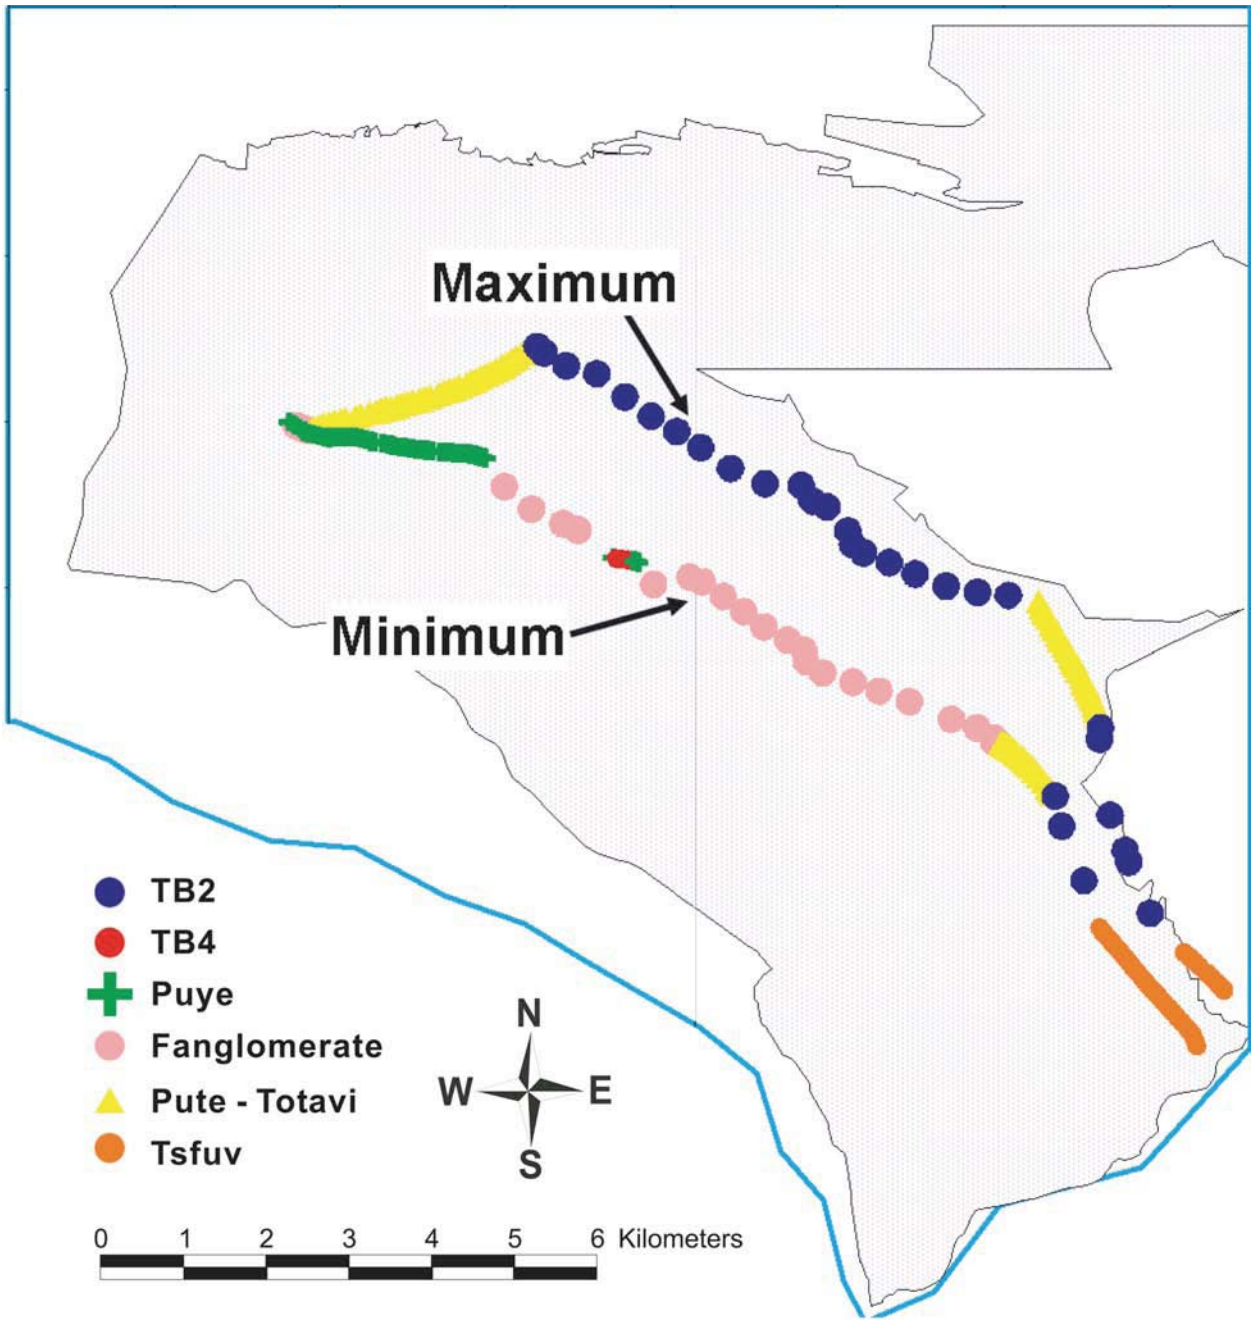

Figure 4-32. Results of predictive analysis, showing the possible range of flow directions (farthest northward and farthest southward) for sources at TA-16. Colors represent hydrostratigraphic units through which the water is flowing.

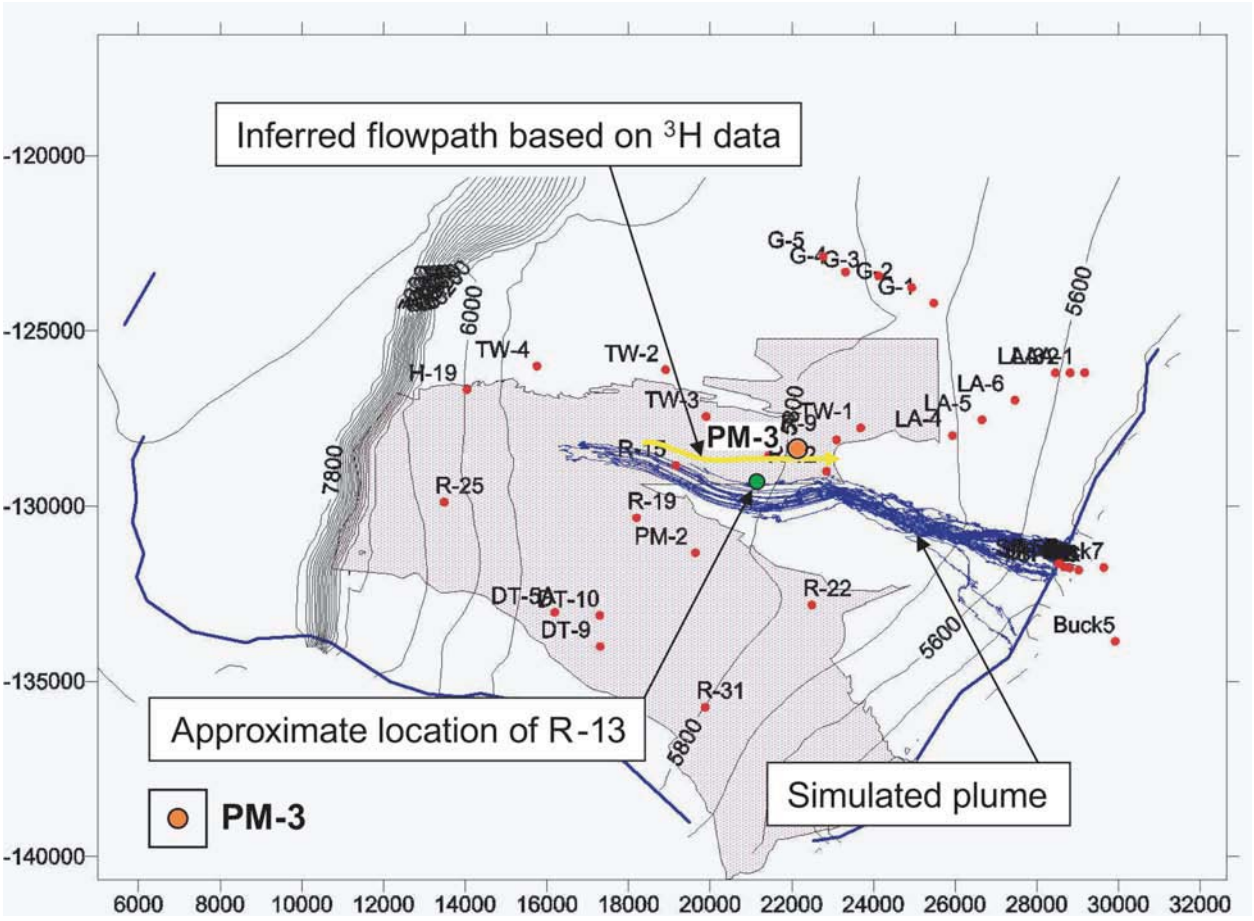

Figure 4-33. Predicted plume migration for sources released at the water table below Mortandad Canyon, based on a steady-state, with pumping, flow field.

Recent analyses of transient capture zones in the vicinity of Mortandad Canyon highlight the fact that flow directions and ultimate point of discharge change both in time and distance along the canyon. Solutes reaching the water table at early times (pre-1970s) and at easterly locations along the canyon probably moved to the east, under natural flow conditions and the pull of PM-1. Solutes reaching the water table at later times and further to the west will likely be drawn to the south. If the location and timing of contaminants reaching the water table is uncertain, the optimal monitoring network therefore will include both easterly and south-easterly monitoring locations.

3. Naturally occurring contamination. Some groundwaters in the Española Basin, including waters in the vicinity of LANL, are contaminated by naturally occurring arsenic, uranium, and flouride (McQuillan and Montes 1998; Purtymun 1977). Data collected in lower Los Alamos Canyon suggest that long-term pumping in water supply wells may increase concentrations of naturally occurring uranium (Gallaher et al. 2004).

Ongoing modeling studies, using the basin-scale model coupled with new water chemistry data collected in cooperation with Santa Fe County and the New Mexico Environment Department,

are attempting to understand the geochemical mechanisms that enhance dissolution of trace metals in aquifer rocks and the hydrologic mechanisms that may cause groundwater extraction to exacerbate the problem. Figure 4-34 illustrates an example model simulation, which simulates the spatial distribution of total dissolved solids in the basin. The prediction of a large area of high-salt water in the vicinity of Santa Fe has possible implications for water resource planning for that community, i.e., the cost of treating the high-salt water or finding alternate resources.

4.2.12.3 Category C: Provide guidance in prioritization of data collection activities, highlighting the importance of those data that could most reduce numerical and conceptual model uncertainty.

1. Reducing uncertainty in transport predictions away from TA-16. After the analysis shown in Figure 4-32 was completed, the model was used to determine how new monitoring wells might reduce the uncertainty in flow directions and travel times. Hypothetical wells were added with head data at five different locations near the particle path lines (shown in Figure 4-35) to determine the value of the head data in reducing pathway uncertainty. When the analysis was conducted, head data from R-25 were not yet available; therefore, head data at this well were not included in the analysis. Interestingly, of the five potential well locations, it was head data at R-25 that had the most benefit. The reason for this result is that information about the vertical component of the 3-D head field at R-25 helped the model determine the extent to which flowpaths are horizontal (fast) or three-dimensional (much slower).

2. Capture zone of PM-5. A similar methodology was used to determine the type of data that would be of most benefit to reducing uncertainty in the ability to predict the capture zone of PM-5 (Vesselinov et al. 2002b). A conceptual particle plume was released at a single location at the water table beneath Mortandad Canyon to simulate the transport away from the site. The calibrated model predicted that the particles traveling along the mean pathway would arrive at PM-5 (orange line, Figure 4-36). This model predicted that ~80% of the particles would arrive at PM-5. By varying recharge parameters and aquifer properties in a large number of possible combinations, within calibration constraints, a wide range of possible model predictions was generated. This analysis showed that parameter uncertainty was sufficiently great so that either 0% or 100% capture was also possible (blue and green lines, respectively, on Figure 4-36). Figure 4-37 illustrates the full plume migration in the 0% capture scenario. The analysis determined that better information on recharge rates in Mortandad Canyon would have the most benefit to reducing predictive uncertainty. The caveats to this study include the following: (1) possible recharge rates were not constrained to be within the bounds provided by existing studies of recharge, and (2) the method of modeling recharge probably overestimates the impact of local recharge on local head gradients.

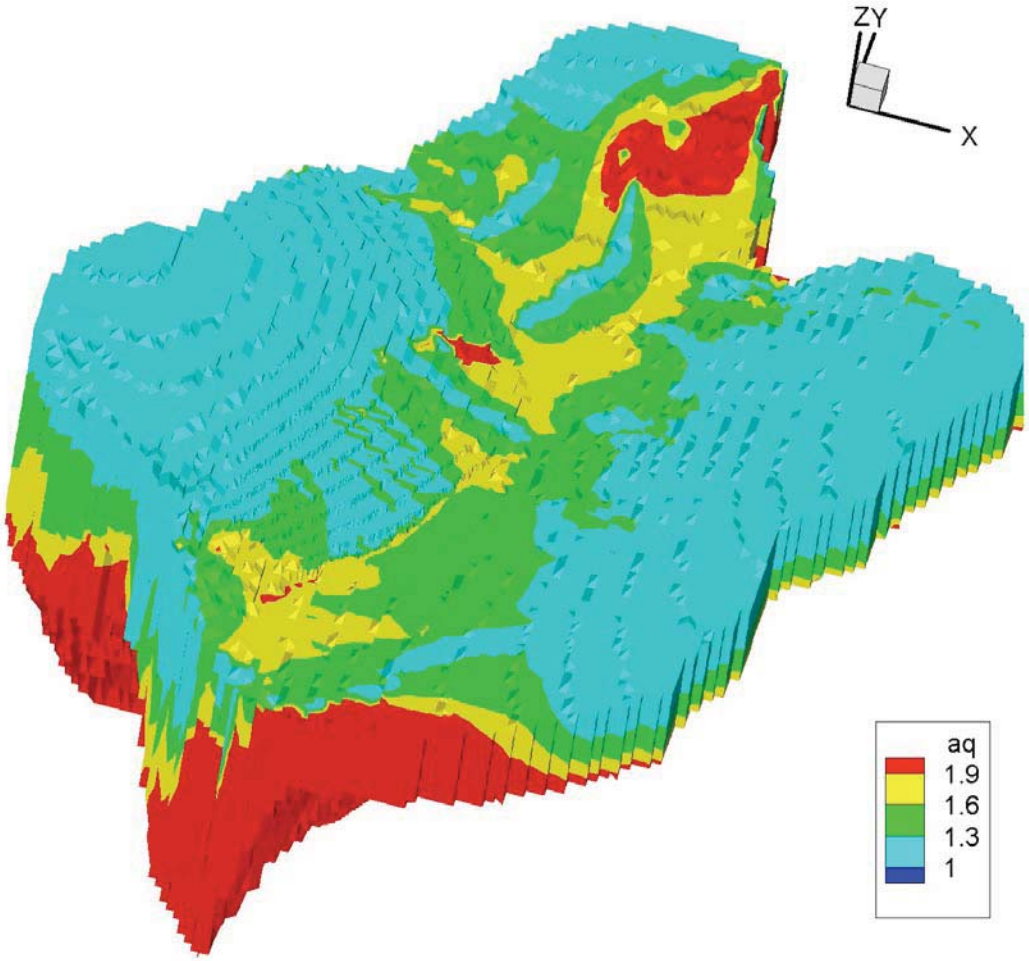

Figure 4-34. Predicted total dissolved salts in the groundwater at steady state, using a simple model of mineral dissolution. Red areas show the zones of relatively old water that are not mixing with fresh water.

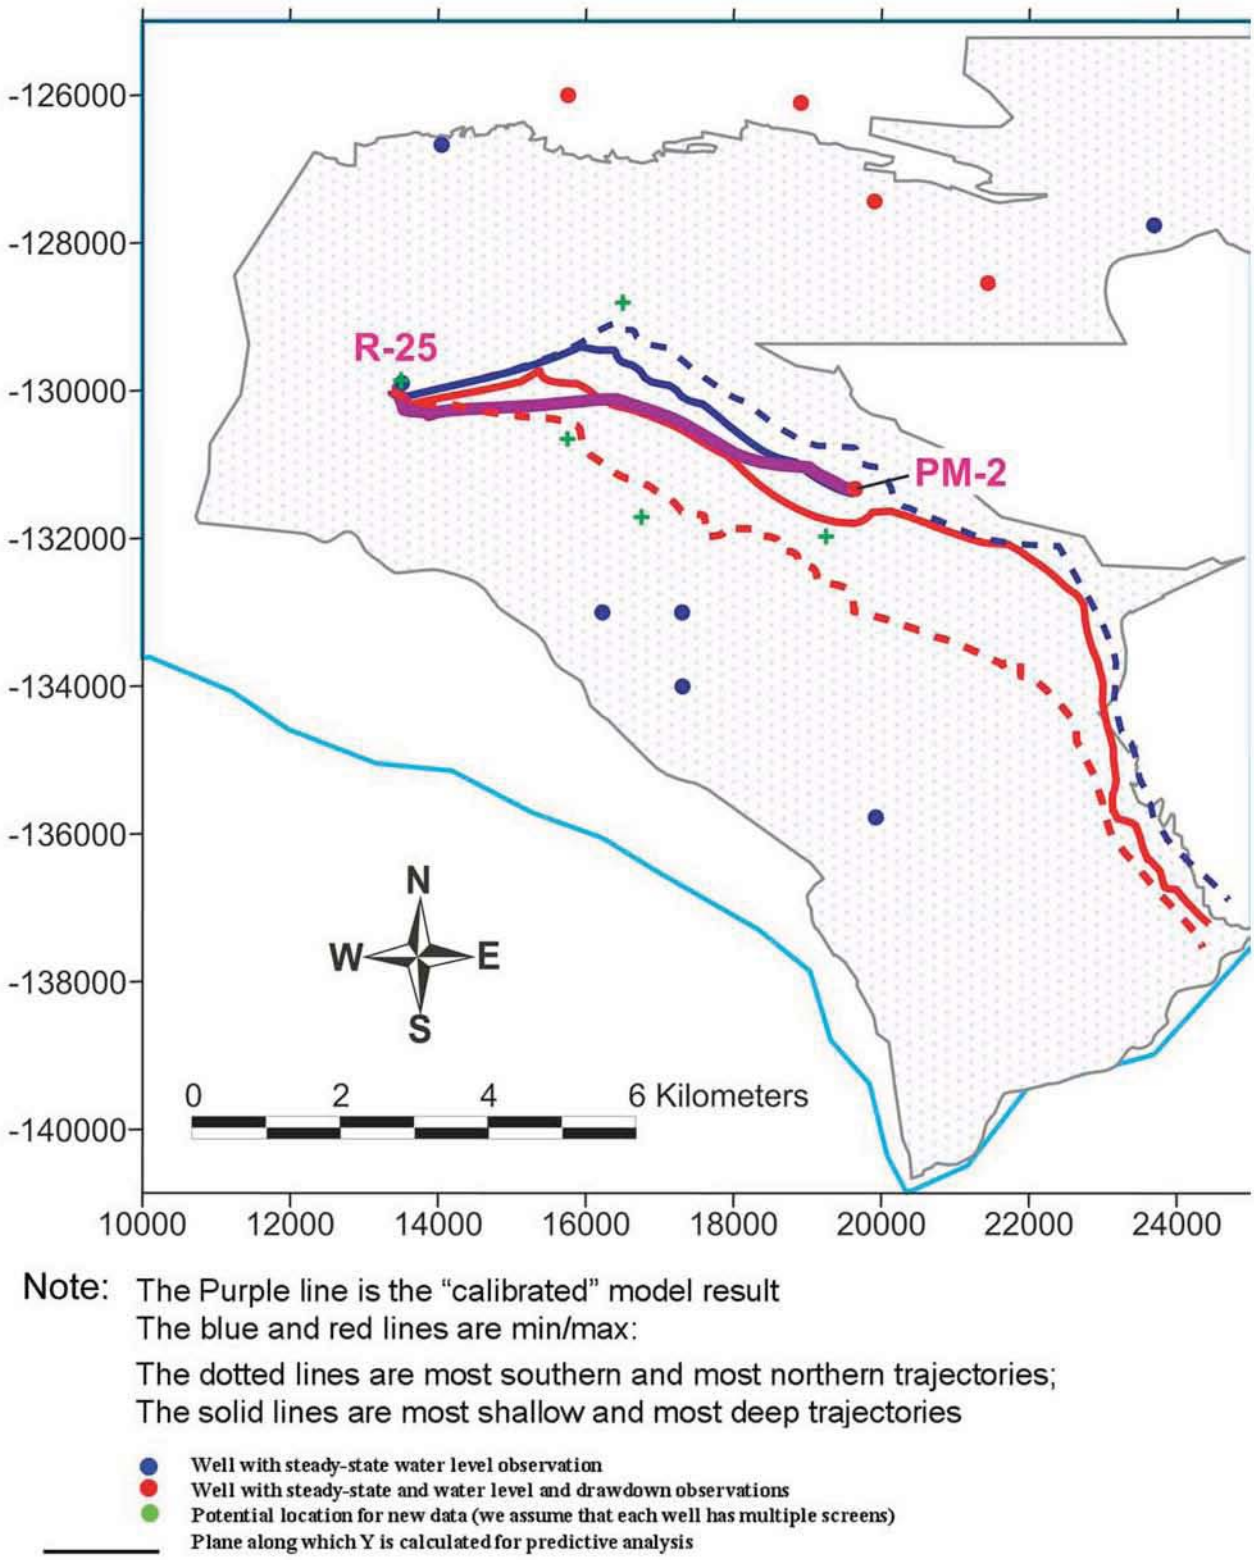

Figure 4-35. Location of hypothetical wells (green crosses) used to evaluate the potential value of head data in reducing uncertainty in flow directions. Solid and dotted lines show range of uncertainty in flow direction (north/south) and flow depth.

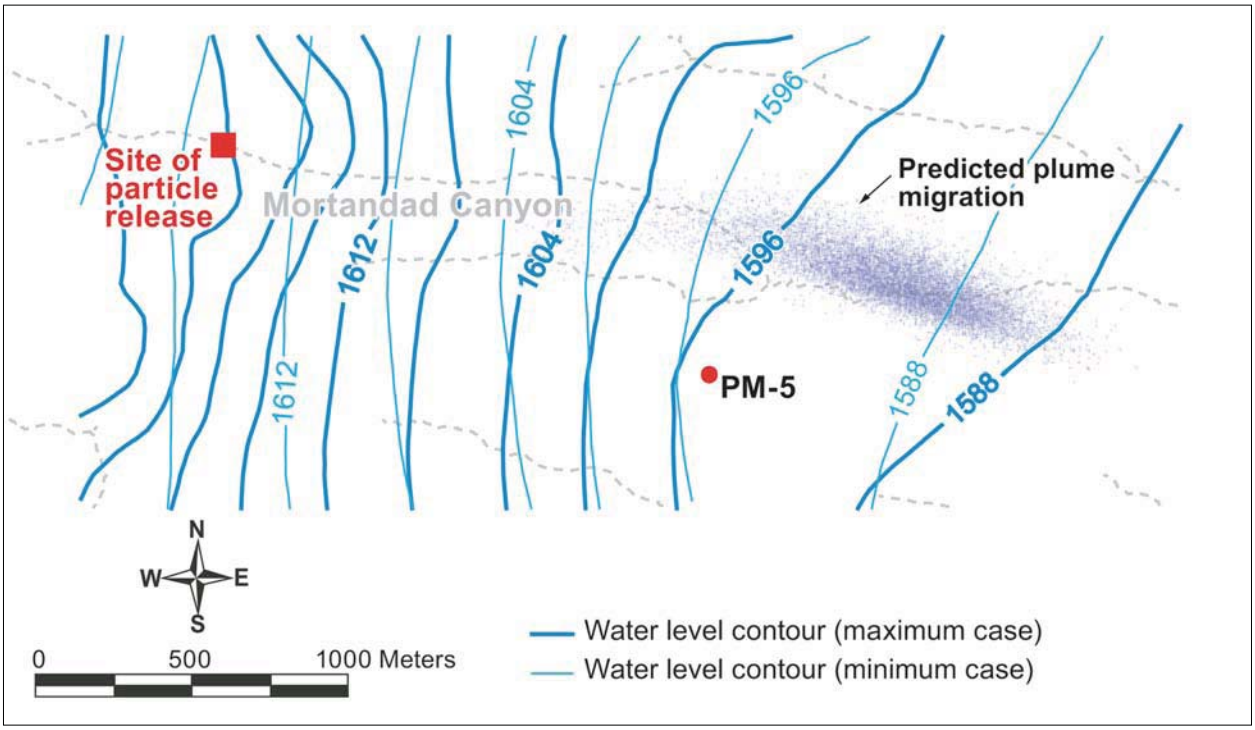

Figure 4-37. Illustration of plume migration for minimum capture by PM 5 (0%). Also shown are the two water table elevations predicted by the minimum and maximum cases.

3. Proposed pump test at O-1. The best way to characterize the hydraulic properties of the aquifer is to conduct a pump test with one or more monitoring wells. It was proposed that characterization well R-5 be drilled very close to O-1 so that a pump test could be conducted. A 2-D radial model was used, with the 3-D geologic model interpolated onto the grid to represent aquifer heterogeneity, to determine the optimal distance the characterization well should be drilled from O-1. Figure 4-38 shows the radial grid, and the predicted drawdowns as a function of distance from O-1, using a variety of model assumptions and parameters (8 cases). The range of suggested distances from the well that came from this analysis was 100–400 m. Ultimately, the well was sited at a greater distance for other purposes and no pump test was conducted. This test will be feasible when well R-3 is constructed closer to O-1.

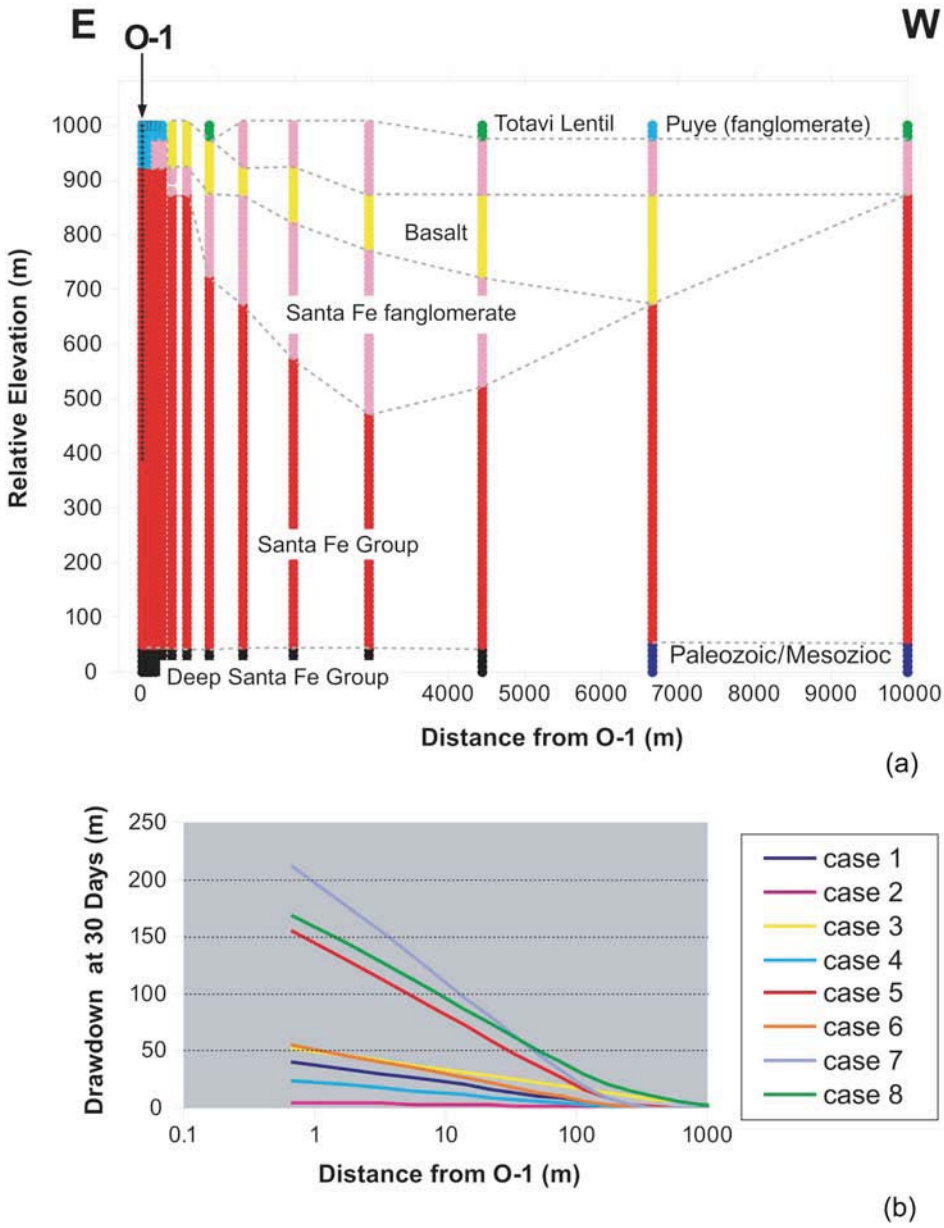

Figure 4-38. (a) Hydrostratigraphic units in the vicinity of well O-1, interpolated onto radial grid; (b) Predicted drawdowns at the top of the aquifer, for eight cases.

5.0 CONCLUSIONS

5.1 Summary

This report has described the geology, hydrology, and geochemistry of the Pajarito Plateau, based on empirical observations and modeling analyses. The purpose of this description is to provide a basis for evaluating and, and if necessary, designing an enhanced monitoring network capable of detecting contaminants. In order for a monitoring system to detect contaminants, an understanding of how contaminants reach groundwater and how contaminants move through groundwater is required. This section draws together the information present in the previous sections to establish a conceptual model of contaminant transport through the hydrogeologic system. This conceptual model is the basis for relating the work to evaluation of risk (Section 5.2) and the monitoring implications described in Section 5.3.

In overview, the contaminant transport conceptual model is one in which contaminants reach points of potential exposure in the regional aquifer only if the following conditions are met:

- Mobile contaminants have been released to the environment
- There are natural or anthropogenic water inputs to carry contaminants downward
- Vadose zone hydrogeologic controls are present, including enhanced infiltration and lateral pathways
- Flow-field modifications are present to influence transport of contaminants in the regional aquifer.

The following subsections draw together the observations and analyses that explain and support these conditions for contaminant transport.

5.1.1 Presence of Contaminants

Imprinted on the natural variations in chemistry is the presence of contaminants historically released since the early 1940s when Laboratory operations commenced. While the contaminants are at concentrations largely below regulatory standards or risk levels, they demonstrate the presence of pathways for groundwater flow and contaminant transport from the surface to deeper groundwater. The impacts to groundwater at the Laboratory have occurred mainly where effluent discharges have caused increased infiltration of water. The depth to which chemical constituents move in the subsurface is determined partly by their chemical behavior: nonreactive constituents move readily with groundwater, while reactive or adsorbing constituents move a shorter distance.

In most cases where effluent sources have been eliminated, groundwater concentrations of non-reactive discharged contaminants have decreased far below previous levels (e.g., nitrate, tritium, and perchlorate) in alluvial groundwater. These mobile contaminants move readily through the subsurface and are detected within perched intermediate zones and at the regional water table beneath several canyons, including Pueblo Canyon, Los Alamos Canyon, Sandia Canyon, Mortandad Canyon, and Cañon de Valle. In the case of reactive or adsorbing chemicals, the concentrations in the alluvial groundwater remain elevated significantly above background levels

after elimination of discharges or other contaminant source terms (e.g., excavation and removal of contaminated sediments). These include constituents such as strontium-90 and the actinides (americium-241, plutonium-238, and plutonium-239, 240) (Section 3.1.2).

Lateral flow and transport through surface water and in the alluvial systems are rapid with respect to other subsurface hydrologic processes on the plateau. Rates of lateral transport are even higher during surface flow events, which occur more frequently in the larger wet watersheds than in other areas of the plateau. Sorbing species transport slowly in alluvial waters and more commonly migrate down the canyon floor by sediment transport (LANL, 2004a; Lopes and Dionne, 1998; Solomons and Forstner, 1984; and Watters et al., 1983). Since some of the wet canyons that cross Laboratory land have received liquid-waste discharges from outfalls, the alluvial systems act as line sources for both water and contaminants to the deeper vadose zone beneath such canyons (Section 2.5.2.2).

Data for conservative (nonreactive) constituents (tritium, nitrate, perchlorate) in alluvial groundwater support the conceptual model that this groundwater has a short residence time and conservative contaminants do not accumulate in alluvial groundwater. The time-trend pattern for these contaminants shows a high level when they were being released, followed by a sharp decline in concentration to nearly nondetectable levels when the source was eliminated. Past values of tritium and nitrate in alluvial groundwater in DP, Los Alamos, Pueblo, and Mortandad Canyons exceeded the 20,000 pCi/L mean concentration level (MCL) (Rogers 1998). Because of improvement in effluent quality, values this high do not occur today in these locations (Section 3.2.3.1).

Data for adsorbing constituents (strontium-90, plutonium-239, 240) illustrate the conceptual model of contaminant adsorption onto alluvial sediments. The time- trend pattern for the adsorbing contaminants shows a decline in concentration when the source is cut off, followed by maintaining a fairly constant low concentration in the groundwater due to cation exchange. The highest measured strontium-90 activity was approximately 500 pCi/L in Acid Canyon surface water in 1960. With no present source, levels have dropped dramatically and strontium-90 is now consistently detected at low activities, below 1 pCi/L in alluvial groundwater (Section 3.2.3.1).

Data showing low levels of tritium activity in intermediate perched groundwater support the conceptual model that alluvial groundwater affected by effluent discharges is a principal source of recharge and contaminants for the intermediate perched groundwater. The highest values of tritium in intermediate perched groundwater are found where effluent discharges have occurred. Tritium time-series data also support a conceptual model that groundwater in the intermediate perched zones may have short residence time. In the absence of effluent discharge from TA-45 as a tritium source in Pueblo Canyon, tritium in the intermediate perched zone sampled by well TW-2A fell rapidly during the 1980s (Figure 3-13). This suggests that tritium associated with the former TA-45 treatment plant infiltrated the canyon floor and migrated vertically, at least to the depth of the intermediate perched zone at TW-2A, but had no continuing source when the TA-45 treatment plant was shut down (Section 3.2.3.2).

The distribution of tritium in the regional aquifer supports the conceptual model that surface effluent discharges have caused the instances where Laboratory contaminants are found at depth.

In most cases, the highest regional aquifer tritium values are found near where effluent discharges have occurred, but are much lower than values observed in overlying alluvial or intermediate perched groundwater. Elevated 3H in regional aquifer samples has been observed at wells O-1, TW-1, TW-3, TW-8, LA-1A and LA-2 (Rogers et al. 1996b), as well as in several wells drilled during the hydrogeologic characterization program (Section 2.7.3.1.1).

The fundamental condition that contaminants should have been released for groundwater contamination to occur is illustrated by the distribution of conservative (that is, nonreactive) groundwater contaminants. Generally, compounds like RDX, tritium, perchlorate, and nitrate move readily with the groundwater because chemical reactions do not retard the movement of these compounds or decrease their concentrations, although the activity of tritium does decrease due to radioactive decay. Semireactive constituents (uranium, strontium-90, barium, some HE compounds, and solvents) whose movement is slowed or their concentrations are decreased by geochemical processes and strongly reacting constituents (americium-241, plutonium, and cesium-137) that are nearly immobile are not found above background levels in intermediate perched groundwater or the regional aquifer (Section 3.2.1).

5.1.2 Water Inputs

Sufficient water input in a canyon system is a critical condition for transporting anthropogenic constituents. In most cases where Laboratory anthropogenic constituents are found at depth, the setting is either:

- Canyons where natural water input is high (Pajarito, Water, and Cañon de Valle)
- Canyons where anthropogenic water input is high (Pueblo, Los Alamos, Sandia, Mortandad)
- Mesa-top sites where large amounts of liquid effluent have been discharged (such as retention ponds or outfalls) (Cañon de Valle and Water canyons) (Section 3.2.2).

Wet canyons receive large runoff volumes, either through channeling of precipitation or through wastewater discharges. This runoff, in turn, creates surface-water flow along canyon bottoms, which subsequently infiltrates to form near-surface, alluvial water bodies (Section 2.4.2.1). The highest net infiltration rates are estimated to occur in canyons, especially those that head in the mountains, with magnitudes of up to a few hundred millimeters per year caused by channelized runoff. In contrast, much lower net infiltration rates occur across mesas and in the smaller canyons that head on the plateau (Section 2.4.2.1).

The infiltration rate estimates from canyon-bottom alluvium and mesa-top sites are consistent with the estimated infiltration rates inferred from moisture content profiles. In Section 4.1.3.2, numerical models for wells LADP-3 and LADP-4 in Los Alamos canyon are presented showing that moisture profiles reflect the conceptual model of high infiltration in canyons and low infiltration on mesas. That analysis also shows that the uncertainties associated with such estimates are quite high (in the range of a factor of 3). However, by combining moisture content, tracer or contaminant profiles, and water budget information, a more constrained estimate has been achieved (Section 2.5.1). The resulting net percolation rates beneath the alluvial systems of

wet canyons to the underlying unsaturated zone are expected to be among the highest across the plateau, approaching meters per year (100–1000 mm/yr) (Kwicklis et al. 2005) (Section 2.5.2.2).

The alluvial groundwater present in several canyons has a small volume relative to the annual volume of runoff or effluents, does not extend beyond the LANL boundary, and is generally completely refreshed by recharge on a time scale of about a year (Section 3.2.3.1). The Kwicklis et al. (2005) study shows that about 23% of the infiltration occurs from canyon bottoms on the plateau at lower elevations, including 14% of the total in streams that flow at least partly within LANL boundaries.

Although relatively small volumetrically compared to mountain recharge to the west, aquifer recharge occurring locally on the plateau is important to the assessment of flow paths of potentially contaminated water. Tritium data confirms that relatively young water is present in the aquifer (Rogers et al. 1996b), indicating fast pathways through the vadose zone beneath LANL. Kwicklis et al. (2005) used vadose zone occurrences of ^{3}H to estimate the time-dependent transport velocities from which they derived the infiltration rates to the regional aquifer. They found that, in Mortandad Canyon, infiltration rates as high as 2000 mm/yr during periods of large volumes of effluent discharge decreased to 100–200 mm/yr when effluent discharge flow rates were reduced. These observations and analyses confirm that local recharge in canyons is an important component of the recharge distribution for the plateau (Section 2.7.3.1.1).

The presence of water, either natural or from the discharge of effluents to canyons or mesa-top locations in the Laboratory's semiarid setting, initiates or increases downward percolation of water. Even under unsaturated flow conditions, this percolation may move significant volumes of water to the regional aquifer within a few decades.

5.1.3 Vadose Zone Hydrogeologic Controls

The third condition that controls the distribution of groundwater contaminants is the presence of vadose zone hydrogeologic controls. The controls considered most important in influencing contaminant distribution and transport are: near- surface circumstances that enhance infiltration, potential pathways in the vadose zone (e.g., basalts), and transport through intermediate perched groundwater.

Infiltration rate affects the movement of anthropogenic constituents from the surface to groundwater. As described in Section 2.5.3, undisturbed Bandelier Tuff has a very low infiltration rate. On mesas, the predicted travel times are variable, but for the most part are greater than 1000 years, ranging from 1000 to 5000 years on the eastern portions of the Laboratory to 20,000 to 30,000 years in the western region. Areas that have other geologic units (particularly basalt units or Puye Formation) or fractured units exposed in the canyon bottom have higher, or enhanced, infiltration rates. In addition, the vadose-zone thickness decreases with increasing distance down canyon, due to thinning of the Bandelier Tuff (Section 2.2.9). Where the Otowi Member of the Bandelier Tuff is thick, infiltration rates are quite low. However, on the eastern side of the plateau, the Otowi Member thins to 0 to 100 feet, reflecting both the general thinning of the Otowi Member away from its caldera source and thinning of the ash-flow

tuffs over the Cerros del Rio highland on the east side of the plateau (Section 2.2.9.1). The eastern portions of canyons with thinned or absent Otowi Member have enhanced infiltration. Infiltration rates of 1500 to 2000 mm/yr are estimated for the confluence of Los Alamos and Pueblo Canyons, a consequence of infiltration directly onto Puye fanglomerates or fractured basalts (Section 2.7.3.1.1.).

Enhanced infiltration is especially true for the eastern portion of deep wet canyons because their canyon bottom elevations are 45 to 60 m lower than smaller canyon systems on the plateau. Thus, the deepest canyons extend to stratigraphic horizons having higher infiltration rates because of increased fracture flow. Contaminants transported down canyon via surface flow or through the alluvial groundwater system often percolate through a geologic column consisting primarily of basalt and Puye Formation fanglomerate with little or no overlying tuff. Downward percolation is believed to be more rapid in the basalt than through moderately welded tuff (Section 2.2.8). Thus, these wet canyons have thinner vadose zones and a smaller portion of the flow path with matrix-dominated flow. Los Alamos and Pueblo Canyons have regions in the vicinity of their confluence in which the Bandelier Tuff is thin or nonexistent. Water infiltrates directly onto basaltic rocks or the Puye Formation, thereby yielding rapidly downward flow through fractures or preferential flow channels. The predicted travel times are especially short (5 to 10 years) in these locations (Section 4.1.2.1).

Other instances of enhanced infiltration include the Cañon de Valle and Water Canyon, where rates up to 1000 mm/yr are estimated for areas associated with the Pajarito fault zone. Anthropogenic alterations can also enhance infiltration, for example sediment ponds in Mortandad Canyon and ponds in Cañon de Valle.

In contrast to the Bandelier Tuff, the basaltic rocks clearly exhibit rapid flow through fractures and other fast pathways, so that the permeability of the matrix rock is essentially irrelevant to the rates of water percolation (Stauffer and Stone 2005). Fracture flow occurs because of the orders-of-magnitude lower matrix permeabilities of these rocks, compared to the Bandelier Tuff (Section 2.4.1). The upper surface of the Cerros del Rio basalt is irregular, with a broad highland that extends from north to south under the east-central portion of the Laboratory, largely buried beneath the Bandelier Tuff. The presence of the Cerros del Rio basalt in the vadose zone provides potential lateral fast pathways in the vadose zone (Section 2.2.8). These hydrogeologic factors, compounded by the relatively high deep-percolation rate in wet canyons, likely yield the fastest vadose-zone travel times for contaminants from the land surface of the plateau to the regional aquifer. Transport to the regional aquifer beneath wet canyons is predicted to be on the order of decades to hundreds of years (Section 2.5.2.2).

The water-quality impacts by effluent releases on alluvial groundwater extend in a few known cases to intermediate perched groundwater at depths of a few hundred feet beneath these canyons. Since the contaminated alluvial groundwater bodies are separated from the intermediate perched groundwater by hundreds of feet of dry rock, pathways within the vadose zone are likely present in those canyons. There are two end-member conceptual models for flow within an intermediate perched water zone:

- *Low-velocity, virtually stagnant water resting in a perching horizon within a local structural or stratigraphic depression.* Water percolates very slowly out the bottom of

this zone or spills over the sides of the depression. This configuration views perching horizons as barriers that slow the downward percolation of water. In several wells, intermediate saturated zones thought to represent perched groundwater were screened but failed to produce significant water. These occurrences may represent cases where zones of limited extent were substantially drained when the perching horizon was penetrated during drilling. Once the stagnant water is depleted in an initial round of sampling, there is insufficient recharge upstream to keep the zone saturated.

- *High-velocity, laterally migrating water that travels on top of the perching horizon.* This conceptualization suggests that once groundwater reaches a perched zone, it rapidly percolates laterally along high-permeability pathways until the perching horizon pinches out or is breached by high-permeability features, such as fractures or lateral changes in lithology. In this scenario, water could move in stair-step fashion from one perching horizon to another. There are no confirmed instances of large-scale, lateral vadose zone pathways beneath the Pajarito Plateau at depths greater than the alluvial groundwater. However, the case of lateral flow through the wet, mountain-front mesas at TA-16 suggests that this possibility does exist at greater depths. Although the TA-16 observations are categorized as shallow for the purposes of this discussion because they discharge via springs in the local canyons, it could be argued that deep pathways with flow geometries similar to those of the mountain-front mesa or today's alluvial groundwater zones are evidence for the possibility of deeper fast pathways elsewhere (Section 2.6.2.4).

The site-wide vadose zone transport model predicts that regions of relatively rapid travel times are present in the following canyons: Pajarito Canyon near White Rock, a portion of Cañon de Valle, Mortandad Canyon at the Radioactive Liquid Waste Treatment facility, middle and lower Los Alamos Canyon, large portions of Pueblo Canyon, and Guaje Canyon (Section 4.1.2.3).

Hydrogeologic controls influence movement of anthropogenic constituents through the vadose zone. The presence of geologic units that enhance infiltration, that act as pathways, or are conducive to perching groundwater and forming intermediate perched groundwater appears to be an important condition for groundwater contaminants to be transported to the regional aquifer.

5.1.4 Regional Aquifer Transport

Relatively little contamination reaches the regional aquifer from the alluvial groundwater bodies, and water quality impacts on the regional aquifer, though present, are low. Flow field modification is considered important in controlling anthropogenic constituent distribution in the regional aquifer. Anthropogenic constituents that enter the regional aquifer near pumping wells are predicted to have much shorter travel times than those outside the influence of pumping.

The LANL regional aquifer model was used to produce a map of velocities at the water table. These velocities are *highly uncertain* and are used only to illustrate a few key points. First, given the heterogeneous nature of the aquifer, groundwater velocity is likely to vary considerably over short distances. There are two areas with relatively high permeability ($K > 3$ m/day): the north-central aquifer beneath LANL (wells TW-2, R-4, TW-3, R-11, R-28, and R-13) and the south-central aquifer beneath LANL (R-19, screen 6, DT-10, DT-9) (Section 2.4.2.3).

The fastest velocities are in the basalts where fracture flow (very low porosity) is assumed. Basalt straddles the water table in two areas. The most extensive is located in the south-central part of the plateau, where as much as 195 ft of saturated Pliocene Cerros del Rio basalt occurs at the top of the regional zone of saturation in well DT-10 and 290 ft occurs in well R-22 (Figure 2-10). A smaller region of older Miocene basalts straddles the water table in a north-trending zone extending between wells R-12 to R-5.

Second, flow on the eastern portion of LANL is predicted to be *very* slow. This is due to the very low permeability of the Santa Fe Group, which is prevalent at the water table east of LANL (Section 4.2.12.1). The Tesuque Formation is the primary rock unit making up the regional aquifer in the eastern part of the plateau and in the Buckman wellfield east of the Rio Grande. Bedding within the Santa Fe Group and the Puye Formation is likely to cause higher permeability parallel to the beds than perpendicular to the beds. Large vertical head gradients measured in R wells are evidence of anisotropy. The beds within the Puye Formation range from centimeters to meters in thickness. Most are very low angle, dipping to the east. In contrast, beds within the pumiceous volcaniclastic rocks tend to dip to the southwest (R-20, R-2, R-7, R-19, and R-33). Beds within the Santa Fe Group exposed on the western margin of the plateau dip approximately 2–5^{o} to the west (Golombek et al. 1983). Data from R-16 suggest that shallow layers are very low-angle, but deeper layers dip as much as 25^{o} to the west. Hydrologic modeling and pump test analysis suggests that vertical permeability is 100 to 1000 times lower than horizontal permeability in the Santa Fe Group (Hearne 1985; McAda and Wasiolek 1988; Keating et al. 2003). (Section 2.4.2.3)

The regional aquifer conceptual model incorporates data from recent large-scale (30-day) pumping tests. Individual drawdown and recovery water levels in responsive wells demonstrate that the regional aquifer surrounding PM-2 is vertically anisotropic with pronounced resistance to vertical propagation of drawdown at shallower depths. Hydraulically, the aquifer behaves like a semiconfined aquifer at depth with leaky units located above (and perhaps below) a highly conductive layer (Section 2.7.5). It appears that there are water-table conditions near the water table, but leaky-confined aquifer behavior deeper down, although the degree to which the uppermost phreatic zone and the deeper, leaky-confined aquifer are hydrologically connected is unknown. The regional aquifer can be thought of as a compartmentalized aquifer with water from plateau recharge traveling laterally in the phreatic zone as the upper compartment and a lower compartment, which contains deeper groundwater flow as the leaky-confined aquifer that is isolated to some degree from the overlying compartment.

The contaminant pathways in the regional aquifer depend heavily on the strength of the hydrologic separation of the two compartments, which translates into how efficiently the pressure drawdown caused by the pumping wells propagates to the water table. Two conceptual alternatives are end members on a spectrum of potential configurations and thus capture the total potential variability.

- Weak hydraulic separation between the shallow (phreatic; water-table) and deep (leaky-confined; pumped) zones does allow pumping drawdown to reach the water table. Hydraulic gradients in the phreatic zone are affected by the pumping and contaminants

are drawn toward the wells. Contaminants are primarily predicted to arrive at water supply wells with a travel time of less than 50 years.

- Strong hydraulic separation between the shallow (phreatic; water-table) and deep (leaky-confined; pumped) zones does NOT allow the pumping drawdowns to reach the water table. Hydraulic gradients in the phreatic zone are NOT affected by the pumping. Contaminants are predicted to bypass the water supply wells and will arrive at the springs with travel time of about 200 years.

Compartmentalized flow with variably separated shallow and deep zones is supported by observations. The recent pumping tests suggest strong hydraulic separation exists, as described in the "strong separation" regional aquifer conceptual alternative. However, it is likely that some downward movement of water and contaminants does occur due to pumping of water supply wells at depth. Occurrences of tritium and perchlorate in O-1 illustrate the point that flow paths between the shallow and deep aquifer water can exist during production. This observation supports deeper pathways near water supply wells, conforming to the "weak separation" regional aquifer conceptual alternative. However, the extent of vertical transport is undoubtedly a function of the local permeability structure between the water table and the pumping interval in the water supply well, which may vary spatially across the plateau.

It is unclear whether it is important to monitoring goals to distinguish between these two alternatives. The first priority is to enable prediction of contaminant transport velocities sufficiently accurately to design an enhanced monitoring network and interpret the results. Either alternative results in lateral transport of contaminants reaching the water table, especially at locations relatively unaffected by municipal water well pumping. It is possible that the more strongly compartmentalized, two-zone aquifer conceptualization might yield more rapid contaminant transport near the water table, with transport pathways that are more lateral and less influenced by municipal water supply well pumping than the weak separation, more uniformly anisotropic case.

5.2 Relation of Hydrogeologic Workplan Results to Risk Assessment

The data, conceptual models, and numerical models resulting from work performed during implementation of the Hydrogeologic Workplan will be used, in combination with data gathered by the Environmental Restoration Program, to perform groundwater risk assessments for LANL-contaminated sites. The risk assessments will synthesize information (and uncertainty) about source term, vadose-zone flow and contaminant transport, and saturated-zone flow and contaminant transport to predict future health effects at receptor locations. They will be performed using a probabilistic approach that incorporates parameter uncertainty and variability, as well as conceptual model uncertainty. Data sets and site information gathered thus far will be used to define uncertainties in the form of parameter distributions and well-defined alternative conceptual models of groundwater flow and contaminant transport. These uncertainties will be propagated through groundwater models and then used in a risk-based decision analysis to identify and rank alternative actions to protect people from potential impacts of groundwater contamination from various release sites.

To construct the probabilistic risk assessment and associated decision analysis, several steps are employed. When using these steps we assume that we have already acquired general knowledge about the site. This assumption is, in general, valid for the main contamination issues on the plateau, based on background information gained during the Hydrogeologic Workplan and Environmental Restoration activities of the past 10 years.

1. *Define the question to be answered*. Examples of the questions might be, "What is the potential, future health risk for water users of municipal supply wells associated with historic effluent releases in canyon X? How can these risks be decreased?"
2. *Define input parameters and construct parameter distributions.* Estimates in the range of model input parameters are made based on field data, historic records and expert judgment. Example distributions might include uncertainty in contaminant masses released as a function of time in geologic and/or in hydrologic properties.
3. *Define conceptual models.* These could be related to source release, to vadose zone and groundwater flow, and to contaminant transport.
4. *Construct numerical models based on information from Steps 1 through 3*. Such models will generally include a vadose-zone and a saturated-zone model.
5. *Sample parameter sets to be used as input for a series of Monte Carlo simulations that capture the ranges of model and parameter uncertainties defined.*
6. *Run probabilistic flow and transport simulations using the numerical models and the parameter sets.*
7. *Use output from flow and transport simulations to calculate health effects or to answer other questions defined in Step 1.*
8. *Perform sensitivity analyses to determine parameters or conceptual models that produce model results indicating potential adverse health effects.*

Steps 2, 3 and 4 rely extensively on work performed for the Hydrogeologic Workplan. Predicted results are compared to field data (concentrations, heads, water content) to verify that model results are reasonable. In addition, in order to create regulator and stakeholder trust in this process and its results, stakeholder input concerning parameter distributions and conceptual models is encouraged.

Based on the sensitivity analysis described in Step 8 above, decision analysis is applied to define the optimal course(s) of action at a particular contaminated site. Such actions may include some combination of cleanup, stabilization, additional characterization, and monitoring. If additional characterization is identified as an action that can reduce risk, the sensitivity analysis yields information not only about which parameters should be better characterized, but also to what degree the uncertainty or variability in a specific parameter should be reduced. If the uncertainty were reduced to within the defined limits through characterization, then an updated risk assessment would calculate reduced risk. The decision analysis may help decrease the cost of future characterization by identifying parameters that do not need to be better characterized. Also, if experts feel that further characterization will not result in decreased uncertainty in a parameter identified in the sensitivity analysis, then that characterization effort might be rejected and an action with a higher probability of success may be pursued instead.

The generic process outlined above will be implemented on a canyon-by-canyon, or site-by-site basis in the future, using information learned from the Workplan and ER activities as a foundation. The conceptual, and for certain sites, numerical models will be formulated based on the knowledge gained and described in Sections 2 and 4 of this report. Thus, the past work becomes the springboard for future risk assessment and decision analysis activities related to groundwater at the LANL site.

5.3 Implications of Hydrogeologic Workplan Findings for Monitoring

The principal motivation for embarking on the Hydrogeologic Workplan was to provide the underlying scientific basis needed to make informed decisions regarding monitoring, remediation, or other actions to provide assurance that the groundwater beneath the Laboratory is protected. The site-wide approach taken in the investigation, both in terms of field-based characterization and modeling, has filled in many gaps in our understanding of the groundwater behavior and pathway directions and rates of migration of contaminants. Characterization wells were drilled for a range of objectives, from the collection of basic hydrogeologic information about the regional aquifer to serving as contaminant-specific and unit-specific sampling wells.

This investigation has led to a vastly improved conceptual understanding of the groundwater systems of the Pajarito Plateau: new concepts have been developed, and previous hypotheses have been confirmed or refined. Although wells have been drilled in a manner that does not preclude their being used in an enhanced monitoring network, the goal was to gather general information required to confirm or refine our conceptual models for groundwater flow and transport. Additional information may be necessary to predict contaminant transport in a particular setting: all sites are unique and require site-specific measurements to reduce uncertainties. However, armed with the improved understanding gained from the Hydrogeologic Workplan activities, we are now able to develop improved groundwater monitoring strategies or conduct more cost-effective detailed studies of individual canyons where initial studies have suggested that groundwater risk may exist.

In this section, we place the results of the findings of the Hydrogeologic Workplan into context by discussing the impact of the conceptual model elements learned in the study to the following questions: How does a particular conceptual model element impact -

- the design of an enhanced groundwater monitoring plan?
- the conduct of a detailed contaminant nature and extent study?
- the application of a remediation strategy?

5.3.1 Alluvial Groundwater

The alluvial system potentially provides a significant pathway for lateral transport at high velocity over great distances. Travel times on the order of a few years are expected in some canyons for contaminants to travel several kilometers from the release location. Tracer tests in Mortandad Canyon and contaminant migration measurements in Los Alamos and Mortandad canyons illustrate this point. A corollary is that within a few years of reducing the source term (reducing the effluent concentration, removing a solid source through remediation, etc.), concentrations of nonsorbing contaminants decrease due to flushing of the alluvial groundwater. These contaminants can enter the underlying vadose zone. Some contaminants such as Sr-90 travel much more slowly in the alluvial system due to retardation resulting from sorption. The contaminant inventory for these constituents is expected to reside mainly in the alluvial groundwater and on sediments (see Section 3).

A number of attenuation processes act to slow or impede the movement of contaminants, but ultimately the spatial extent of contamination within the canyon is limited by the distance traveled by surface and subsurface water. This distance varies seasonally with rainfall and runoff variability, and can be significantly changed from natural conditions by the input of anthropogenic water sources such as LANL effluent discharges or municipal water treatment facilities.

Alluvial groundwater is the potential source for water and contaminants to the deeper vadose zone. Percolation rates to the deeper vadose zone are temporally and spatially variable. Zones of preferential percolation exist, and it is difficult to predict their locations a priori. These zones are probably controlled by the nature of the hydrogeologic properties at the base of the alluvium, topographic conditions of the canyon, and the degree of fracturing of the underlying basement rock. For example, relatively high recharge is thought to be associated with fractures in Los Alamos Canyon near the Guaje Mountain Fault zone and in locations in the vicinity of the low-head weir, where water infiltrates directly into fractured basalts.

Implications of this conceptual model for nature-and extent studies, groundwater monitoring strategies, and remediation are:

- Long-term monitoring of the alluvial groundwater should focus on nonsorbing contaminants such as tritium, perchlorate, and aqueous HE compounds.
- To monitor changes in contaminant concentrations in response to changes in operations or after remediation, frequent samples must be taken to track progress.
- The absence of a contaminant known through historical records to have been introduced into a canyon likely means that the contaminant resides deeper in the system, and has been flushed out of the shallow system once the release was terminated.
- A relatively complete mass balance of released sorbing contaminants can be achieved by focusing on the alluvial sediments and groundwater.
- If a nonsorbing contaminant has been released for many years into a canyon, most of the inventory probably resides in strata below the alluvial system, so remediation techniques

such as permeable reactive barriers in the alluvial system will be addressing only a small fraction of the inventory.

- Sorbing contaminants are accessible to remediation technologies applied to the alluvial system. Technologies requiring a flux of contaminant, such as a permeable reactive barrier, are likely to work slowly, but may be useful, should some type of vadose zone remediation be required.
- In nature-and-extent studies for nonsorbing contaminants, zones of enhanced infiltration must be located using hydrologic studies to understand the different terms in the water budget. Surface water flow data, piezometric measurements of alluvial groundwater heads, and shallow borings that penetrate the underlying bedrock are useful to identify these zones.
- Numerical models of the surface-water/alluvial groundwater system are useful for constraining the estimates of percolation rates to the deeper vadose zone.

5.3.2 Vadose Zone

Transport velocities for nonsorbing contaminants in the deeper vadose zone (below the alluvial systems) are much larger in canyon bottoms than on mesa tops, suggesting that effluent discharges into canyons are the principle threats to the deep groundwater. Localized zones of high water flux from mesas are possible, such as in locations where the surface has been disturbed by human activities, or in faulted regions in close proximity to the Pajarito fault zone. However, most mesas show little, if any, evidence of transport of large quantities of contaminants to great depths. Numerical models of unsaturated zone transport in mesas are consistent with this observation.

Transport of contaminants from the alluvial groundwater zones to the deeper vadose zone can occur in two main rock types: Bandelier Tuff and basalts. Water percolates principally through the matrix pores in the Bandelier Tuff, but drains quickly through fractures and other open void space in the basalts. Fractures in the Tshirege Member of the Bandelier Tuff at the base of the alluvial systems probably serve as preferential pathways for downward percolation, but water quickly imbibes into the rock matrix, and matrix flow is even more likely in the more homogeneous Otowi Member. The subsurface location of contaminants in the vadose zone is controlled by the local percolation rate from the alluvial system. Although contaminants might be present in the rock pores along the entire reach of a contaminated canyon, the greatest quantities of nonsorbing contaminants will likely be present in zones of enhanced percolation. As discussed in the previous subsection, the locations of these zones are difficult to predict in the absence of detailed studies of the alluvial system.

Where Bandelier Tuff is present, travel times to the regional aquifer are controlled by the percolation flux and the total thickness of the underlying tuff units. Travel times through the tuff units probably range from a few decades to several hundred years. This means that most of the inventory of nonsorbing contaminants probably still resides in the vadose zone. In many vadose zone wells, the location of the contaminant front in the vadose zone has been located in the Bandelier Tuff. However, even where a well defined front exists, contamination is also found in deeper perched zones in the same well or in nearby wells. This suggests that a zone of higher percolation flux supplies the zone, and some lateral flow occurs. This lateral flow may be along

the canyon, but it is just as likely that the well is located nearby, but offset from the zone of highest percolation, and the lateral transport occurs a short distance perpendicular to the strike of the canyon.

Where infiltration occurs directly onto basalts, higher percolation rates are expected, along with much more rapid transport of contaminants to depth. Travel times through the basalts are expected to be a few years. Beneath the basalts and the Bandelier Tuff, the Puye Formation represents a highly heterogeneous vadose zone medium in which preferential pathways are likely. Travel times through the Puye Formation are therefore likely to be small for nonsorbing contaminants.

Sorbing contaminants are rarely detected at depths below the alluvial groundwater, even in locations where they were released coincident with nonsorbing contaminants that are found at depth. Retardation due to sorption is a key delay mechanism in the system. Detailed sampling has not been conducted in the few feet of rock immediately below the alluvial groundwater zone, but it is likely that any sorbing contaminants that have escaped the alluvial system have only migrated a very short distance into the bedrock.

Perched water is commonly found beneath naturally wet canyons or canyons with significant water input from anthropogenic sources. Generally, the perched water is not found to flow underneath the adjacent mesas, although data are somewhat limited. Perching is caused by low-permeability horizons: the downward percolation rate exceeds the saturated hydraulic conductivity of the perching horizon, and water collects or is diverted laterally. The degree of lateral flow within perched zones is uncertain. Lateral diversion will force contaminants to reach the water table at a different location than it entered the deeper vadose zone, but it is unlikely that this location will fall significantly outside the uncertainty zone defined by the alluvial groundwater zone. Travel times are not dramatically affected by the nature of flow in the perched zone. Travel times are controlled by percolation through the Bandelier Tuff, and the details of the flow path beneath these units are relatively unimportant in determining the total travel time to the regional aquifer. Finally, perching horizons provide a convenient means for monitoring the extent of transport of contaminants in the vadose zone.

Implications of this conceptual model for nature-and extent studies, groundwater monitoring strategies, and remediation are:

- Monitoring of the performance of waste sites located on mesas will probably turn up little contamination at great depth: sampling ports located in the vadose zone directly beneath the waste are probably required to detect contaminants. Given that regional aquifer monitoring to ensure the validity of this conclusion will probably be required, we should attempt to combine monitoring with characterization or other goals to maximize the utility of the well.
- Wet canyons with contaminants are the locations to focus monitoring.
- In zones where contaminants percolate directly into basalts, contamination has traversed the vadose zone, and characterization efforts should focus on the regional aquifer. Further characterization of nature and extent in the basalts of the vadose zone will not yield as

useful information in locations where contaminants have already reached the regional aquifer.

- Long-term monitoring of the intermediate groundwater should focus on nonsorbing contaminants such as tritium, perchlorate, and aqueous HE compounds.
- Sorbing contaminants can be checked on a less frequent basis because to date they have not traveled to significant depths, making the rapid breakthrough of high concentrations to the perched zones or the regional aquifer very unlikely.
- Given the range of travel times through the vadose zone, it is critical, if risk-based approaches are taken, that decision makers settle on the time period of regulatory interest. Without this definition, studies will not be appropriately focused, and misplaced characterization activities are likely to be the result.
- Although downward migration along the entire length of a wet canyon may occur, unequal percolation rates along the canyon lead to zones where greater depths of penetration of contaminated water has occurred, including all the way to the water table. Uncontaminated regional aquifer water at one location does not guarantee that the regional aquifer is clean at another location in the same canyon.
- Monitoring wells should be located near or downgradient of zones of preferential percolation determined from alluvial and vadose zone studies. In canyons posing significant risk, a higher density of shallow intermediate wells should be considered to pinpoint the preferential transport pathways than in canyons with lower risk potential.
- Given that the lateral displacement of contaminants in perched zones will not add large additional uncertainty to the location of contaminant arrivals at the water table, nor will travel times be much affected, there is no compelling reason to study in detail the nature of flow and transport in the perched zones if the regional aquifer water is ultimately of greatest interest for groundwater protection. Characterization of pathways closer to the surface is more cost effective and definitive, and should bound the lateral extent of transport above the regional aquifer.
- Contaminant inventories are likely to be small in most perched zones compared to the thick, unsaturated regions in which contaminated water is held in the matrix pores. Therefore, the perched zones are not good candidates for remediation by pump-and-treat methods because only a small fraction of the inventory will be accessed. An exception might be the large perched zone containing HE contamination at TA-16. If such a technique is attempted, better hydrologic characterization of the intermediate zones are required than we have obtained to date.
- Perched zones are targets of opportunity for acquiring contaminant concentration data, making them useful in nature and extent studies.
- Remediation of contaminants in the unsaturated rock of the vadose zone is not likely to be successful using available technologies. Water residing in matrix pores cannot be pumped, and most contaminants of interest are not volatile. Gas-phase nutrients could possibly be delivered to increase biological activity and induce bioremediation of organic contaminants, but the large spatial extent of contamination in the vadose zone probably renders such concepts impractical unless a single zone of preferential flow and transport is discovered.

5.3.3 Regional Aquifer

The regional aquifer represents the most likely groundwater accessible to humans via the municipal water supply wells and the springs that discharge at the Rio Grande in White Rock Canyon. The focus of this summary is on the elements of the conceptual model most directly connected to the migration of contaminants in the regional aquifer. Aquifer processes and measurements in the broader regional context were established in Section 2.7 and models were presented in Section 4.2.

Local recharge on the plateau on Laboratory property is a relatively small fraction of the total recharge, but is critical to understand for its implications for contamination from historical and current Laboratory operations. Some of the recharge focused along canyons contains contaminants from the Laboratory. This water potentially represents a source term for regional aquifer contamination.

To date, several observations have been made of contaminants reaching the regional aquifer. Conditions facilitating possible rapid downward migration to the regional aquifer are described in the previous subsections. High percolation rates, typically enhanced by anthropogenic water sources, and/or relatively thin or non-existent Bandelier Tuff at the surface are the conditions most likely to result in present-day regional aquifer contamination of nonsorbing constituents. Future contamination at additional locations is expected over a period of decades to centuries as more of the contaminant inventory reaches the water table.

There are no definitive observations of sorbing contaminants having reached the regional aquifer via a groundwater pathway. This fact further supports the concept of retardation due to sorption as the principal retardation mechanism for many contaminants.

Measured concentrations of nonsorbing contaminants in the regional aquifer are much lower than their concentrations in the effluent discharges or in the alluvial groundwater. This is the case even for samples collected near the top of the regional aquifer, where it might be expected that dilution due to dispersive mixing with regional aquifer water would not have taken place to as great a degree as further downgradient and at greater depth. Significant dilution of these plumes has occurred, assuming that samples are representative of the maximum concentrations and are not affected by mixing in the borehole. Borehole mixing and dilution is expected in municipal water supply wells, but is likely to be less prevalent in characterization-well samples with short screens.

Lateral flow directions in the regional aquifer are defined by the potentiometric surface constructed on the basis of new measurements in the shallow regional aquifer in characterization wells drilled during the characterization program. Flow directions are generally west to east or southeast across the plateau. Detailed gradients at scales smaller than the distance between wells are more uncertain, and might be affected by local recharge conditions and pumping of nearby water supply wells. Deeper in the aquifer, gradients and flow directions are uncertain due to lack of deep wells. Different conceptual models lead to either (1) easterly flow paths with water upwelling and discharging at the Rio Grande, or (2) more southerly flow

paths with water leaving the Española Basin via interbasin flow to the Albuquerque Basin. Data to distinguish between these two mechanisms are lacking.

Heads decrease with depth in most characterization wells on the plateau, and this condition is probably magnified by pumping of municipal water supply wells, whose screens are located well below the water table. While this condition might imply that contaminants at the water table should move downward, the hydrodynamics of the system are a function of the rock properties as well as the gradient. At some locations we find significant resistance to flow in the vertical direction, leading to compartmentalized zones that are connected only weakly to each other. Phreatic (unconfined water-table) conditions are present near the water table, whereas the aquifer exhibits behavior consistent with leaky-confined conditions at greater depths. The common observation of water-table conditions on the plateau, the depth-dependent response to pumping during multiple-well hydrologic tests, and the persistent head declines in the deeper aquifer in response to pumping are evidence of this behavior. More information is needed to determine if this is a ubiquitous feature of the aquifer.

This conceptual model means that contaminant transport pathways are not necessarily downward in the regional aquifer. In the extreme, a ubiquitous low-permeability barrier separating the phreatic zone from the deeper zone would render the downward component of the gradient meaningless: downward flow would be negligible, and contaminants hitting the regional aquifer would travel laterally along the streamlines defined by the potentiometric surface. The reality is almost certainly more complex, with thin (in the vertical), laterally discontinuous, low-permeability heterogeneities creating increasingly confined conditions with depth. In such a situation, pathways to the depths of water supply well screens are also likely.

Linear transport velocities are a function of the effective porosity of the medium as well as the groundwater flux. Porosity estimates are best made using interwell tracer tests, but these tests have not yet been conducted in the regional aquifer. Heterogeneous flow at larger scales will tend to result in lower effective porosity estimates than what is measured in cores or with borehole logging tools due to preferential flow. All else being equal, lower effective porosity leads to higher velocities and shorter travel times.

Implications of this conceptual model for nature-and extent studies, groundwater monitoring strategies, and remediation are:

- Contaminant detections in the regional aquifer are spatially variable, with detects and non-detects in the same canyon. Given that contamination has probably arrived at the regional aquifer only at a few locations, contaminant monitoring locations in the regional aquifer must be selected using an approach that integrates information of alluvial, vadose zone, and regional aquifer.
- More detailed investigations along canyons with risk-significant contamination are needed to pinpoint the spatial locations of the fastest pathways to the regional aquifer. Locations within or downgradient of these zones are good locations for contamination monitoring. The concept that the canyons are a line source of recharge is a good starting point, but more detailed information is needed to place monitoring wells.

- Contaminant detections in the regional aquifer will probably continue to be at low concentrations, and changes in time of these values will be gradual. Sampling frequency can thus be relatively long without missing important information.
- Long-term monitoring of the regional aquifer groundwater should focus on non-sorbing contaminants such as tritium, perchlorate, and aqueous HE compounds.
- Sorbing contaminants can be checked on a less frequent basis because to date they have not been detected with certainty in the regional aquifer.
- Contaminants reaching the regional aquifer most likely will travel laterally from their point of entry into the aquifer at the water table. Tortuous pathways to greater depths are also possible, with perhaps only a fraction of the contaminant taking this deeper path, and the rest continuing to travel laterally. Sampling screens in the shallowest portion of the regional aquifer are thus most likely to be well placed to detect contamination. Permeable zones within the first 100 ft or so of the regional aquifer should be the targets for monitoring locations.
- If the water discharging the regional aquifer at the springs in White Rock Canyon is principally water that recharged locally on the plateau, then continued monitoring of these springs for contamination is appropriate. Changes in concentrations are expected to be very gradual, so relatively infrequent sampling is sufficient.
- The extent of downward contaminant migration induced by water supply well pumping is uncertain, ranging from capture of the plume by the supply wells to a shallow, laterally migrating plume unaffected by pumping. Observations at O-1 prove that capture by a water supply well can occur. However, at other locations, weak or non-existent pressure responses in the shallowest screens to pumping from the deeper aquifer suggest that pathways may not exist that connect the shallow and deeper system.
- Given this variability and uncertainty, the concept of a "sentinel well," that is, a well designed to provide advanced warning of supply well contamination, will be difficult to implement. A shallow screen would miss a contaminant transport pathway in which the vertical downward migration occurs upstream of it, whereas a screen at the elevation of the producing zone might miss a vertical pathway located downstream of the monitoring well (including a situation in which the supply well itself is a pathway).
- Monitoring wells designed to be used as sentinel wells must attempt to provide coverage for both types of flow paths. Shallow screens will probably be the best sampling locations for water ultimately discharging at the Rio Grande.
- If pump-and-treat is proposed for a contaminant in the regional aquifer, the system should focus on the uppermost portion of the aquifer, where regional aquifer contaminants are known to reside. More detailed measurements of the hydrologic conditions in the shallow regional aquifer are required to better design monitoring or remediation systems.
- Pumping tests using the water supply wells to induce the pressure response are extremely informative, and should be continued as opportunities present themselves. Each pumped well provides information in the vicinity of that well, so to gain the site-wide knowledge needed, continued testing is required. The tests are not duplicative or redundant: rather, each test provides unique information.

- Tracer tests are the best way to determine the effective porosity of the medium at the field scale. This parameter is needed to convert groundwater flux estimates to a contaminant transport velocity estimate. The Puye Formation and the Cerros del Rio basalts are the most important units in which to conduct these tests, since these are the units encountered at the water table in regions where Laboratory contamination is a concern.
- The regional aquifer flow and transport model must continue to be improved by incorporating new data and concepts. Use of the model to interpret the hydrologic response of the system, to design and interpret the results of the future monitoring program, and in contaminant transport predictive studies requires that models keep up with the new data that will be collected. In the shorter term, available data sets not used in the model development to date, including the pumping tests discussed above, geochemical data, and thermal data, should be incorporated into updated versions of the model.
- For all modeling, including the regional aquifer model, continued exploration of alternative hypotheses should be continued. This statement applies for all aspects of the groundwater model, including those elements not obviously tied to questions of contaminant transport. Groundwater model development is a process in which feedbacks of changes in one portion of the system can affect model performance in unforeseen ways. A philosophy of continuous model improvement should continue to be used to enable higher fidelity predictions as improvements are made.
- Future studies should go beyond current approaches to include a data collection and modeling processes that make the greatest use of opportunities to investigate large portions of the aquifer. These opportunities may include: (1) passive monitoring of aquifer pressures in response to inputs (recharge) and withdrawals (supply well pumping) that occur as a matter of course; (2) incorporation of that information into refined versions of the regional aquifer model; and (3) increasing use of remote data that provides information on large-scale aquifer conditions and properties, including INSAR, airborne electromagnetic data, or gravity data, if initial investigations demonstrate that these techniques provide useful information.

APPENDIX 1-A. REGULATORY FRAMEWORK

1-A-1. Hydrogeologic Workplan Background

The Hydrogeologic Workplan was intended to collect data necessary to comprehensively address DOE, federal, and state groundwater requirements. The groundwater requirements are for characterization and monitoring. The intent of the Hydrogeologic Workplan was to characterize the hydrogeologic setting to the degree necessary to evaluate the existing monitoring network and design an enhanced network, if necessary.

1-A-1.1. DOE Orders

LANL, in compliance with DOE Order 5400.1, published a Groundwater Protection Management Program Plan (GWPMP) on March 6, 1995 (LANL 1995a). A subsequent draft of the plan including revisions and dated January 31, 1996, was approved by DOE/AL on March 15, 1996 (LANL 1996a). The GWPMP provides background information on the hydrologic setting and programs in place at LANL; describes groundwater issues and solutions; and lays out business and implementation plans. The GWPMP concluded that the number and distribution of wells was insufficient to monitor the groundwater beneath LANL. The Hydrogeologic Workplan (LANL 1998) was intended in part to address the monitoring network issue by collecting data necessary to design an enhanced monitoring network.

1-A-1.2. RCRA Permit and HSWA Requirements

In 1986, the Environmental Protection Agency (EPA) authorized the State of New Mexico to operate a hazardous waste management program under the RCRA. The New Mexico Environment Department (NMED) issued a Hazardous Waste Facility Permit (Permit NMD890010515) to the Laboratory on November 8, 1989. At that time, both EPA and NMED retained administrative authority for the permit: EPA for the portions of the permit that were affected by the RCRA Hazardous and Solid Waste Amendments (HSWA) enacted in 1984, and NMED, for the parts of the permit that were unaffected by HSWA. In March 1990, the EPA issued a HSWA module to LANL's permit (known as Module VIII) and, in January of 1996, authorized NMED to act as administrative authority for that module. Thus in 1996 NMED became the sole administrative authority for the Laboratory's Hazardous Waste Facility permit.

The activities described in the Hydrogeologic Workplan support the appropriate Resource Conservation and Recovery Act (RCRA) and the New Mexico Hazardous Waste Act monitoring and corrective action decisions that have yet to be made at LANL. This investigation phase comes before and provides the basis for formal RCRA monitoring that may be warranted. The general RCRA requirements for characterization and monitoring are provided in the following sections.

1-A-1.3. RCRA Monitoring Requirements

LANL is currently in compliance with RCRA groundwater monitoring requirements. The monitoring requirements under RCRA are different for "regulated units" and for other "solid

waste management units" (SWMUs). This discussion will address both types of monitoring requirements.

RCRA Monitoring Requirements for Regulated Units

"Regulated units" are surface impoundments, waste piles, land treatment units, and landfills that received hazardous waste after July 26, 1982. The "regulated units" that remain at LANL and have not undergone clean closure (all hazardous waste residues and contamination have been removed) are

- Area G in Technical Area 54 (TA-54),
- Area H in Technical Area 54 (TA-54), and
- Area L in Technical Area 54 (TA-54).

(Note: Open Burning/Open Detonation units in the High Explosives corridor at LANL, although not considered "regulated units", once permitted may be subject to similar groundwater monitoring requirements as "regulated units" if they pose a threat to groundwater).

The monitoring requirements for regulated units are described in the RCRA regulations in sections 40 CFR 264.90 to 40 CFR 264.100. The monitoring for regulated units is divided into three structured, sequential monitoring programs: (1) a program for detection, (2) a program for compliance, and (3) a corrective action program. The requirements of these monitoring programs are summarized generally in Table 1-A-1. According to the regulations, monitoring of these units may be waived under the following conditions:

- The unit presents no potential impact to groundwater.
- The unit has been clean closed.
- The regional administrator/state director has granted a groundwater monitoring waiver.

Groundwater-monitoring waiver demonstrations for all of LANL's "regulated units" (including those that had not yet been clean-closed) were submitted to NMED in the 1980s and early 1990s. In May 1995, the NMED issued a letter to LANL indicating that there was insufficient information on the hydrogeologic setting upon which to base approval of the groundwater-monitoring waiver demonstrations, and the waiver demonstrations were denied (NMED, 1995a). By letter dated August 17, 1995 NMED required that a site-wide hydrogeologic characterization be completed that would satisfy both the RCRA "regulated units" and the HSWA module requirements. (Section III. A. 1 of the HSWA portion of the RCRA permit requires that the hydrogeologic setting be characterized) (NMED, 1995b). Thus, groundwater monitoring requirements for LANL's "regulated units" can be addressed by the completion of the site-wide hydrogeologic characterization described in the Hydrogeologic Workplan.

In response to the NMED letters, the Laboratory submitted the Hydrogeologic Workplan to NMED in 1996 and received NMED approval on May 22, 1998. The Hydrogeologic Workplan describes a 7-year characterization effort for groundwater on a Lab-wide basis with the objective of developing sufficient understanding of the hydrogeology to design an adequate detection monitoring network or to resubmit waiver demonstrations for some or all of the units.

Table 1-A-1.
RCRA Groundwater Monitoring Programs for Regulated Units

Monitoring Program	Triggered by	Purpose	Requirements	Definition	Result
Detection (40 CFR 264.98)	Required for all owners/operators of facilities that treat, store, or dispose of hazardous waste 40 CFR 264.91(4), unless exempt by waiver	Detect releases that are a threat to human health or the environment	Monitor for indicator parameters, constituents, or reaction products. Monitoring to be based on the type, quantity, and concentration of waste constituents in the unit; mobility, stability, and persistence in unsaturated zone; detectability in groundwater; and concentration in background	"Detected" defined as statistically significant evidence of contamination based on comparison of groundwater quality upgradient and unaffected by unit to groundwater that passes beneath the unit measured at the point of compliance	If "detected", institute compliance monitoring program
Compliance (40 CFR 264.99)	Whenever hazardous constituents to which the ground water protection standard applies are detected at a compliance point 40 CFR 264.91(1)	Document that a release from a unit is above a standard. Determine compliance with ground water protection standard	To determine whether regulated units are in compliance with the groundwater protection standard by monitoring constituents and their associated concentrations specified in the permit at the POC for the prescribed period. The groundwater protection standard specifies: list of constituents; concentration limits; point of compliance; period of compliance	"Exceeded" defined as statistically significant evidence of increased contamination	If ground water protection standard concentration limits are being exceeded, institute corrective action program
Corrective Action (40 CFR 264.100)	Whenever the groundwater protection standard is exceeded 40 CFR 264.91(2) & (3)	To ensure that corrective action has successfully brought regulated units into compliance with the groundwater protection standard	Requires action taken to prevent hazardous constituents from exceeding concentration limits and a groundwater monitoring program established to demonstrate effectiveness	Same as for Compliance Monitoring Program	If concentrations are being exceeded, re-evaluate corrective action

Monitoring Requirements for Solid Waste Management Units

The applicability of RCRA groundwater monitoring requirements to units not defined as "regulated units" at 40CFR264.90 (or subpart X units that pose a threat to groundwater) is described at 40 CFR 264.101. For these types of solid waste management units (SWMU), there are no specific monitoring requirements; however, preamble language suggests that repetitive monitoring may be necessary to determine the efficacy of a remedy in the event a release is determined to be a threat to human health or the environment. In addition, characterization to determine if a release to groundwater has occurred and to what extent, if any, such release threatens human health or the environment may be necessary. LANL's ENV-ERS Project conducts the investigations necessary to determine if releases have occurred and if a release represents an unacceptable risk to human health and the environment.

There is a requirement for hydrogeologic characterization at Section III.A.1 of the HSWA module of the RCRA operating permit. The work conducted under the Hydrogeologic Workplan was intended to fulfill this requirement for characterization, in addition to the requirements for "regulated units".

In summary, there are no RCRA monitoring requirements for SWMUs that are not "regulated units", unless a release requiring corrective action is identified through characterization. LANL was in the process of characterizing the hydrogeologic setting, identifying releases, determining the extent of any releases, and evaluating the risk posed by any releases through activities associated with the HWP and Module III of the HSWA module.

In 2005, NMED, DOE, and UC signed a Compliance Order on Consent (NMED 2005). The order replaces the site-wide characterization requirements of the Hydrogeologic Workplan with wells intended to investigate the nature and extent of contaminant releases from sources. The data and information gained through implementation of the Hydrogeologic Workplan are invaluable to planning and implementing the site-specific corrective action investigations required by the Order on Consent (NMED 2005).

1-A-2. Technical Objectives of the Hydrogeologic Workplan

As previously stated, the Hydrogeologic Workplan was developed in response to NMED letters requiring a better understanding of the hydrogeologic regime in order to evaluate the need for groundwater monitoring. Specifically, NMED identified four issues that needed to be resolved (NMED 1995b):

- Individual zones of saturation beneath LANL have not been adequately delineated and the "hydraulic interconnection" between these is not understood.
- The recharge area(s) for the regional and intermediate aquifers and any associated effects of fracture-fault zones with regard to contaminant transport and hydrology have not been identified.
- The groundwater flow direction(s) of the regional aquifer and intermediate aquifers, as influenced by pumping of production wells, are unknown.
- Aquifer characteristics cannot be determined without additional monitoring wells installed within specific intervals of the various aquifers beneath the facility.

In addition, the Hydrogeologic Workplan was intended to satisfy the characterization requirements in the HSWA module. Table 1-1 is a crosswalk of HSWA module requirements, how they have been addressed, and which sections of this report contain that information. The technical objectives of the Hydrogeologic Workplan were intended to be comprehensive with respect to groundwater regulatory requirements for characterization and potential future monitoring.

The questions posed by the NMED were large-scale hydrogeologic questions that were open-ended – it was unclear how much data would be required to resolve them. To address this issue, the Hydrogeologic Workplan focused the hydrogeologic investigations on information needed to understand potential contaminant transport and exposure from "aggregates": groups of potential release sites (PRS) that are geographically close and had similar waste-generating processes. The Data Quality Objective (DQO) process was employed to develop the data collection and analysis portions of the Hydrogeologic Workplan. The DQO process was developed by the Environmental Protection Agency to ensure that data collected are adequate for decision-making (EPA, 1994). The first step in applying the DQO process was developing a decision flow chart that specified the decisions for which data were necessary (Figure 1-A-1). The decision statements were in answer to the following questions:

- Are the alluvial groundwaters and uppermost subsurface waters at contaminant concentrations greater than a regulatory limit or risk level?
- Is the intermediate perched zone groundwater at contaminant concentrations greater than some regulatory limit or risk level?
- Is the regional aquifer, as affected by canyon systems, impacted by contaminant concentrations greater than some regulatory limit or risk level?
- What are the pathways for exposure to contaminants from sediments associated with alluvial groundwater and uppermost subsurface water?
- Are there sufficient source terms to cause contamination if moved along pathways to the regional aquifer within a compliance time frame?

The first three decisions are used to determine whether groundwater currently exceeds standards. The last two decisions establish whether pathways exist that may allow contamination to occur in the future. Each decision had several subordinate questions that required some data to answer. The decisions cannot be resolved until data sufficient to answer each subordinate question is available. For example, for the decision: "what are the pathways for exposure to contaminants from alluvial sediments and uppermost subsurface water?" the subordinate questions are as follows:

- Does significant recharge occur from near surface to underlying groundwater bodies?
- Do we know the hydraulic properties of the alluvium?
- What are the retardation factors of alluvial sediments?
- Do we understand groundwater movement from alluvial water to intermediate perched zones?

- Do we understand groundwater movement from intermediate perched zones to the regional aquifer?
- Are fractures and faults important contaminant transport pathways for liquids in canyons?

Although there were numerous subordinate questions and decisions, the data needed to resolve them were primarily water quality information from alluvial, intermediate, and regional aquifer groundwater, hydrologic properties, and geochemistry. Modeling tools were identified as critical to analyzing the data collected and to guide further data collection.

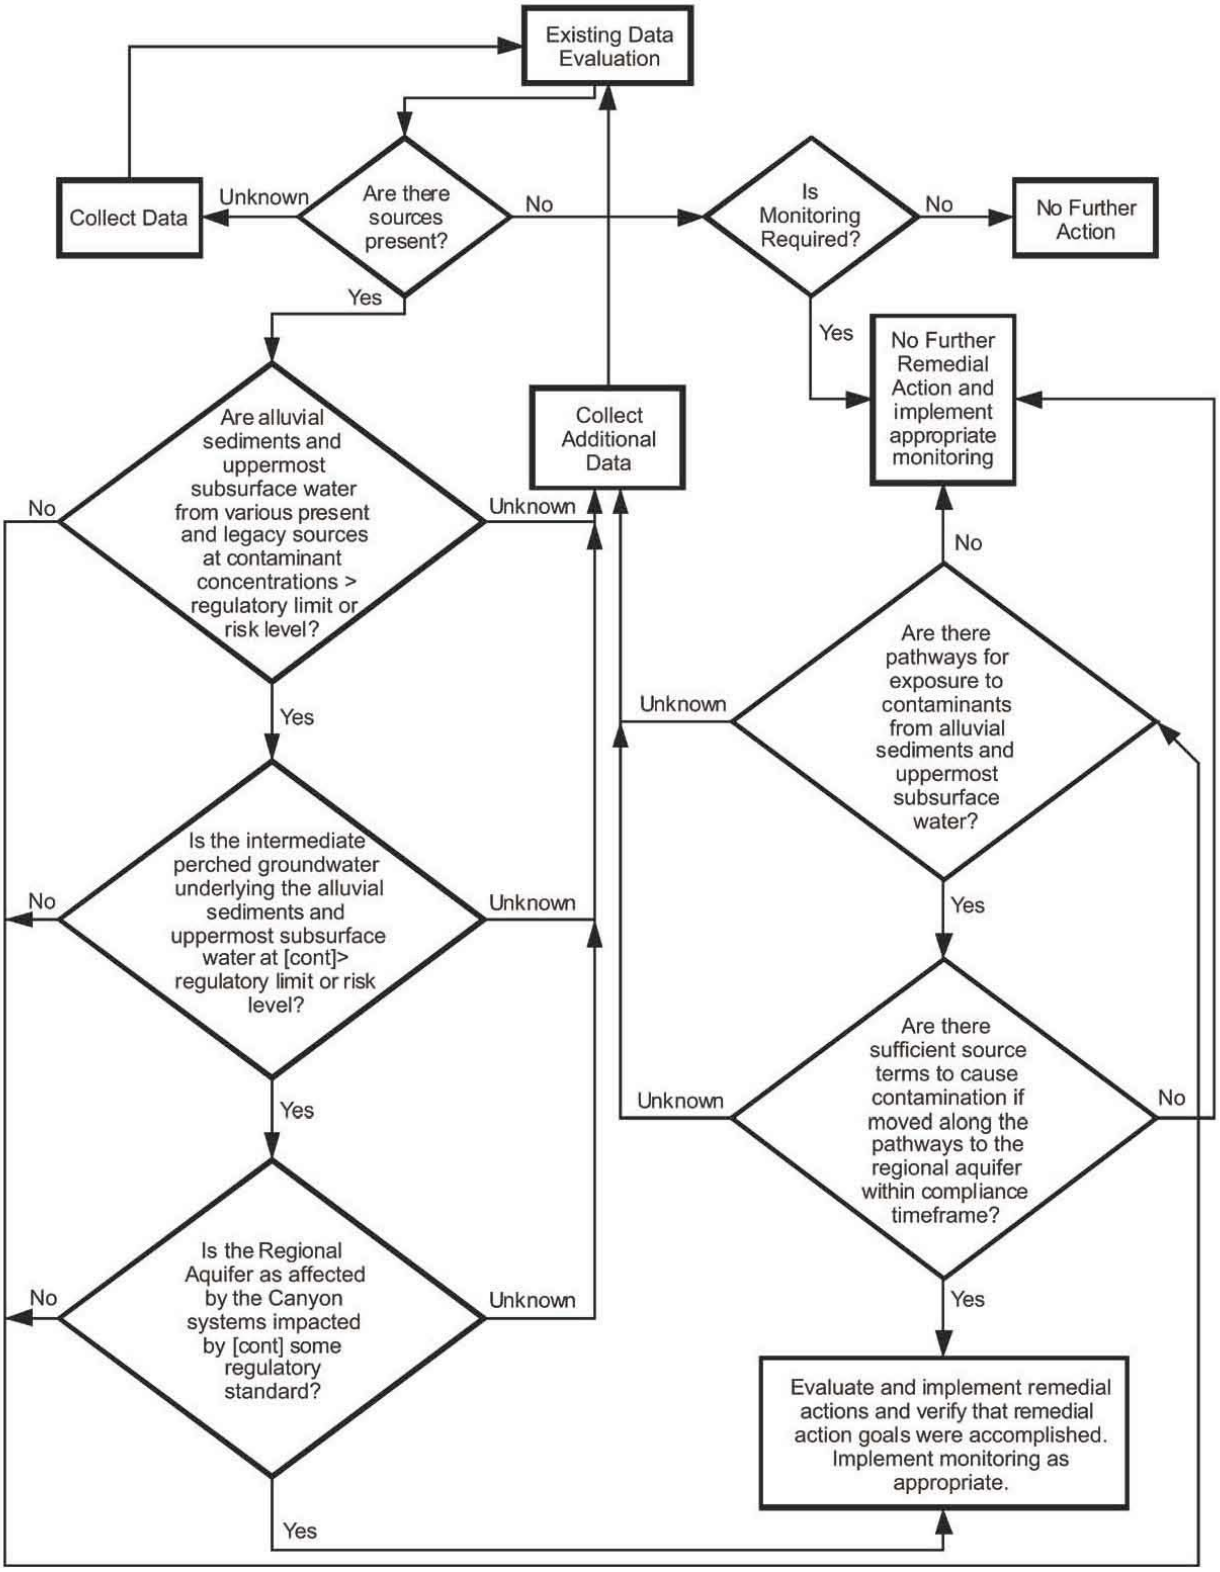

Figure 1-A-1. Flow chart used for hydrogeologic characterization decisions (LANL, 1998).

1-A-3. Hydrogeologic Workplan Data Collection Approach

The data collection approach described in the Hydrogeologic Workplan utilized an iterative approach that incorporated new information and data into the site conceptual model as it became available. This method enabled effective decision-making for aggregates to occur in the characterization process on a step-by-step basis. This approach was developed, in part, to resemble EPA's concept of the limit of the waste management area as described in the definition of the point of compliance. In this definition, it is acceptable to circumscribe several units with an imaginary line when locating the point of compliance, a vertical surface at the hydraulically downgradient limit of the waste management area at which the groundwater protection standards apply (New Mexico Annotated Code, Title 20, Chapter 4, Part 1, (20 NMAC 4.1) Subpart VI, 264.95(2)). The aggregate approach bounded similar areas in a manner that supported not only logical hydrogeologic characterization but process and regulatory application as well.
